Rationale: Acquired diaphragm muscle weakness is a key feature in several chronic conditions, including chronic obstructive pulmonary disease, congestive heart failure, and difficult weaning from mechanical ventilation. No drugs are available to improve respiratory muscle function in these patients. Recently, we have shown that the calcium sensitizer levosimendan enhances the force-generating capacity of isolated diaphragm fibers.

Objectives: To investigate the effects of the calcium sensitizer levosimendan on in vivo human diaphragm function.

Methods: In a double-blind, randomized, crossover design, 30 healthy subjects performed two identical inspiratory loading tasks. After the first loading task, subjects received levosimendan (40 μg/kg bolus followed by 0.1/0.2 μg/kg/min continuous infusion) or placebo. Transdiaphragmatic pressure, diaphragm electrical activity, and their relationship (neuromechanical efficiency) were measured during loading. Magnetic phrenic nerve stimulation was performed before the first loading task and after bolus administration to assess twitch contractility. Frequency of diaphragm electrical activity was evaluated to study the effects of levosimendan on muscle fiber conduction velocity.

Measurements and Main Results: The placebo group showed a 9% (P = 0.01) loss of twitch contractility after loaded breathing, whereas no loss in contractility was observed in the levosimendan group. Neuromechanical efficiency of the diaphragm during loading improved by 21% (P < 0.05) in the levosimendan group. Baseline center frequency of diaphragm electrical activity was reduced after levosimendan administration (P < 0.05).

Conclusions: The calcium sensitizer levosimendan improves neuromechanical efficiency and contractile function of the human diaphragm. Our findings suggest a new therapeutic approach to improve respiratory muscle function in patients with respiratory failure.

Keywords: diaphragm; muscle weakness; calcium sensitization; levosimendan

Impaired force generation of the respiratory muscles has been recognized in a variety of diseases, including chronic obstructive pulmonary disease (COPD) and congestive heart failure, and in critically ill patients (1–7). The pathophysiological substrate of diaphragm dysfunction in these disorders is multifactorial and includes muscle fiber atrophy and contractile protein dysfunction (3, 8–11). We found that diaphragm muscle fibers of patients with COPD display reduced sensitivity of the contractile proteins to calcium (9, 12). In other words, more calcium is needed to develop the same amount of force as in the non-COPD diaphragm, resulting in impaired contractile efficiency of the diaphragm muscle. Subsequent studies have shown that calcium sensitivity is also reduced in the diaphragm of animal models of congestive heart failure and prolonged mechanical ventilation (2, 13). Despite a better understanding of respiratory muscle dysfunction in chronic diseases, no drug is available to improve respiratory muscle function in humans.

Levosimendan is a clinically used calcium sensitizer that has been approved to enhance cardiac contractility in patients with acute heart failure. Clinical studies have shown that levosimendan improves cardiac function in these patients (14). Levosimendan enhances the binding of calcium to troponin C, thereby improving the responsiveness of myofilaments to calcium. Accordingly, a greater amount of force is generated for the same level of cytosolic calcium, resulting in enhanced contractile efficiency. Levosimendan has vasodilatory properties mediated by the opening of the ATP-sensitive potassium (KATP) channels (15).

Recently, we have shown that levosimendan enhances calcium sensitivity of permeabilized muscle fibers obtained from the human diaphragm, including patients with COPD (12). However, the effects of calcium sensitizing on the human diaphragm in vivo have not been studied. Based on our in vitro data (12), we...
hypothesize that levosimendan improves contractile function of the human diaphragm in vivo through calcium sensitizing and that levosimendan would decrease muscle fiber conduction velocity of the diaphragm through its effects on $K_{\text{ATP}}$ channels in diaphragm fibers. We tested this hypothesis in a double-blind, placebo-controlled, crossover design in healthy subjects performing inspiratory loading tasks. Some of the results of this study have been previously reported in the form of an abstract (16).

METHODS
We enrolled 30 healthy volunteers in this trial. The protocol was approved by the ethical committee of the Radboud University Nijmegen Medical Centre and registered at ClinicalTrials.gov (NCT01101620). All subjects gave their informed consent.

Esophageal Catheter
Diaphragm electromyographic activity (EMGdi), esophageal pressure (Pes), and gastric pressure (Pga) were obtained with a multielectrode esophageal catheter with two balloons (details are provided in the online supplement). Transdiaphragmatic pressure (Pdi) was calculated as $\text{Pga} - \text{Pes}$.

Magnetic Stimulation and Maximal Inspiratory Effort
Cervical magnetic stimulation of the phrenic nerves was performed to measure twitch Pdi (Pdi$_{\text{tw}}$) and compound muscle action potential of the diaphragm (CMA Pdi). Details about the stimulation protocol are provided in the online supplement.

Maximal voluntary Pdi (Pdi$_{\text{max}}$) was measured as mean Pdi in the first second during a maximal inspiratory effort against a closed valve at functional residual capacity.

Inspiratory Loading Task
Each subject performed two identical loading tasks, one before and one after administration of the study medication. Sitting in upright position with uncast abdomen, subjects breathed through a mouthpiece while wearing a nose clip. Subjects performed intermittent inspiratory maneuvers of 10 seconds against a closed valve (near-isometric contractions) followed by 7 seconds of unloaded breathing. Duty cycle was imposed by a sound signal, and subjects were asked to target 40% of Pdi$_{\text{max}}$. Visual feedback of Pdi was provided. Total loading task duration was 10 minutes. During loading, EMGdi and Pdi were recorded continuously, as well as in unloaded conditions approximately 5 minutes before and after loading. Respiratory effort sensation was scored with a Borg scale (range, 6–20) at 1, 3, 6, and 9 minutes into loading.

Experimental Protocol
The protocol is presented in Figure 1. Pdi$_{\text{tw}}$ and Pdi$_{\text{max}}$ were measured and followed by the first loading task and 30 minutes of unloaded breathing. After randomization, subjects received levosimendan bolus (40 $\mu$g/kg bodyweight, intravenously) or an equal volume of placebo in 10 minutes. Pdi$_{\text{tw}}$ and Pdi$_{\text{max}}$ measurements were repeated and followed by 30 minutes of continuous levosimendan (0.1 $\mu$g/kg bodyweight/min, intravenously) or placebo infusion. A second loading task was performed while infusing levosimendan (0.2 $\mu$g/kg/min, intravenously) or placebo.

Heart rate, end tidal carbon dioxide (etCO$_2$), and peripheral oxygen saturation (SpO$_2$) were monitored continuously. Blood pressure was measured noninvasively every 10 minutes and during bolus administration each minute. In six subjects, cardiac output was determined by transthoracic echocardiography directly before and after bolus administration.

Data Analysis and Statistics
Measurement variables were analyzed offline in Matlab R2009b (The Mathworks, Natick, MA) (details are provided in the online supplement). The ratio of mean inspiratory Pdi and EMGdi amplitude was calculated as a measure of the neuromechanical efficiency of the diaphragm. Changes in muscle fiber conduction velocity were evaluated using the power spectrum center frequency (CFdi) of the EMGdi (details are provided in the online supplement). Comparisons were made with the appropriate $t$ test. Changes over time during loaded breathing were analyzed using repeated measures ANOVA. Values are means $\pm$ SEM, and $P < 0.05$ was considered significant. Statistical analyses were performed with SPSS 16.0 (SPSS, Chicago, IL).

RESULTS
Baseline characteristics of the subjects (male/female, 23/7; age, 22 $\pm$ 0.4 yr; bodyweight, 74 $\pm$ 1 kg; and body mass index, 23 $\pm$ 0.4 kg/m$^2$) were not different between the placebo and levosimendan groups. All subjects (n = 30) received study medication as dictated by the protocol. One subject was excluded due to technical problems with the esophageal catheter. Two subjects were not able to maintain targeted Pdi (< 30% of Pdi$_{\text{max}}$) during the first loading task and were excluded from data analysis. The remaining subjects (placebo, n = 13; levosimendan, n = 14) were able to keep their targeted Pdi during both loading tasks (44 $\pm$ 1% and 43 $\pm$ 2%), indicating compliance to the protocol. SpO$_2$ was above 96% in all subjects during the study; no supplemental oxygen was given. There were no differences in etCO$_2$ between the placebo and levosimendan group during loaded breathing.

Furthermore, there were no serious adverse events during the experimental protocol. One subject, receiving levosimendan, experienced a mild degree of nausea after completion of the study.

Diaphragm Contractility
Cervical magnetic stimulation of the phrenic nerves resulted in reproducible twitch pressures in all subjects. Data from magnetic stimulation and maximal inspiratory maneuvers, as well as hemodynamic data, are given in Table 1. There was no significant difference in Pdi$_{\text{tw}}$ and Pdi$_{\text{max}}$ between the placebo and the levosimendan groups before study medication.

Figure 2 shows a decreased contractile response of the diaphragm after the first loading task in a subject receiving placebo.

On average, loaded breathing in subjects receiving placebo resulted in significant reductions in Pdi_{tw} (−9 ± 3%; P = 0.01) and Pdi_{max} (−5 ± 3%; P < 0.05). The group receiving levosimendan after the first period of loaded breathing revealed no significant decrease in Pdi_{tw} and Pdi_{max} (Figure 3; Table 1).

Neuromechanical Efficiency of the Diaphragm

In Figure 4, representative tracings of EMG_{di} and Pdi are presented for the first loading task (before study medication) and the second loaded task (with study medication) for both groups. Neuromechanical efficiency of the diaphragm (Pdi/EMG_{di}) in the first loading task was not different between the placebo and the levsimendan groups (both 1.3 ± 0.2 cm H2O/μV) and remained stable throughout the loading task (Figure 5). Neuromechanical efficiency during unloaded breathing and during the second loading task was improved by 21% (P < 0.05, compared with the first loading task) in the levsimendan group, whereas neuromechanical efficiency was not affected in the placebo group (Figure 5). The improved neuromechanical efficiency in subjects receiving levsimendan sustained throughout the entire loading task.

Center Frequency of Diaphragm Electrical Activity

During both loaded breathing protocols, CFdi decreased over time (P < 0.001) (see Figure E1 in the online supplement) in both groups. Administration of levsimendan resulted in a downward shift in baseline CFdi during the second loaded breathing protocol (P < 0.05; Figure E1), whereas placebo did not affect CFdi.

Respiratory Effort Sensation

Respiratory effort sensation increased over time (P < 0.001) during loaded breathing until a score of 16 was reached. Neither levsimendan nor placebo affected respiratory effort sensation.

DISCUSSION

The present study is the first to evaluate the effect of the calcium sensitizer levsimendan on human diaphragm function in vivo. In this double-blind, randomized study, an intervention of loaded breathing resulted in significant loss of diaphragm contractility in the placebo group but not in the levsimendan group, suggesting that levsimendan restored diaphragm contractility. Loaded breathing after drug administration was associated with improved neuromechanical efficiency of the diaphragm in the levosimendan group. Furthermore, levsimendan reduced baseline center frequency of diaphragm electrical activity. Levsimendan was well tolerated with negligible side effects.

Calcium Sensitivity and Muscle Fiber Conduction Velocity: Effects of Levsimendan

Skeletal muscle force develops as intracellular calcium rises and binds to troponin C, resulting in conformational changes in the troponin complex, allowing interaction between actin and myosin to form force-generating cross-bridges. Reuptake of calcium from the cytoplasm into the sarcoplasmic reticulum is a high energy-consuming process (up to 40% of total energy expenditure). Thus, reduced sensitivity of the troponin complex for calcium requires higher levels of cytoplasmic calcium to generate the same amount of force, requiring higher energy consumption and elevated CO2 production.

Levsimendan belongs to a relatively new class of drugs, the calcium sensitizers and is approved in more than 40 countries worldwide to improve cardiac function in patients with acute heart failure (14). Although the loading dose of levsimendan in this study is higher than recommended for the treatment of...
The contractile performance of the diaphragm was evaluated using magnetic stimulation and maximal inspiratory efforts.
and thus increased neuromechanical efficiency of the diaphragm. The subject receiving levosimendan shows decreased neural activation when compared to placebo, there is no change in EMGdi (i.e., neural activation), whereas the subject receiving placebo shows increased neural activation. This suggests these subjects were more difficult to stimulate. Correcting for CMAPdi amplitude abolished the baseline difference in EMGdi amplitude between the groups (data not shown).

To further evaluate the function of the diaphragm, we measured neuromechanical efficiency of the diaphragm (Pdi/EMGdi) during inspiratory loaded breathing. We found that diaphragm neuromechanical efficiency at 40% of Pdimax was constant over time and that CFdi decreased over time during loaded breathing, which are in line with previous data from Sinderby and colleagues (36). We also found that, despite evidence of twitch force loss, the diaphragm neuromechanical efficiency was not reduced in the placebo group during the second loaded breathing task. Thus, the reductions in maximal contractility were not reflected in the decreases in maximal contractility were not reflected in the neuromechanical efficiency during submaximal contractions. Regardless of the reason for this inconsistency, the double-blinded randomized design of the study should ensure that the finding of improved neuromechanical efficiency, which occurred only in the levosimendan group, was not due to bias, carry-over effects, or other subjective influences.

Figure 4. Diaphragm electromyography (EMGdi) and transdiaphragmatic pressure (Pdi) during the first (black) and second loading task (blue) in a subject receiving placebo (A and B) and levosimendan (C and D). Subjects were asked to target 40% of Pdimax. In the subject receiving placebo, there is no change in EMGdi (i.e., neural activation), whereas the subject receiving levosimendan shows decreased neural activation and thus increased neuromechanical efficiency of the diaphragm.

Magnetic stimulation has a clear benefit over voluntary maneuvers because it is effort independent and highly reproducible (34). Values for Pdilw and Pdimax reported in our study are similar to those reported by other groups for healthy subjects (20, 35). Due to coincidence, baseline Pdilw and CMAPdi amplitude were lower (though insignificant) in the levosimendan group (Table 1), suggesting these subjects were more difficult to stimulate. Correcting for CMAPdi amplitude abolished the baseline difference between the groups (data not shown).

In conclusion, the present study demonstrates that the calcium sensitizer levosimendan improves contractile function and neuromechanical efficiency of the human diaphragm. These findings suggest a new therapeutic approach for patients with acute respiratory muscle dysfunction.

Figure 5. Neuromechanical efficiency of the diaphragm (Pdi/EMGdi) before, during (at 1, 3, 6, and 9 min) and after the first and second loading task in the placebo (A) and levosimendan (B) groups. Administration of levosimendan resulted in an increase in diaphragm efficiency ($P < 0.05$) during loaded and unloaded breathing, whereas placebo had no effect on diaphragm efficiency. Data are presented as mean ± SEM (placebo, $n = 13$; levosimendan, $n = 14$).
