The emergence of resistance against current antibiotics calls for the development of new compounds to treat infectious diseases. Synthetic pantothenamides are pantothenate analogs that possess broad-spectrum antibacterial activity in vitro in minimal media. Pantothenamides were shown to be substrates of the bacterial coenzyme A (CoA) biosynthetic pathway, causing cellular CoA depletion and interference with fatty acid synthesis. In spite of their potential use and selectivity for bacterial metabolic routes, these compounds have never made it to the clinic. In the present study, we show that pantothenamides are not active as antibiotics in the presence of serum, and we found that they were hydrolyzed by ubiquitous pantetheinases of the vanin family. To address this further, we synthesized a series of pantetheinase inhibitors based on a pantetheinate scaffold that inhibited serum pantetheinase activity in the nanomolar range. Mass spectrometric analysis showed that addition of these pantetheinase inhibitors prevented hydrolysis of pantothenamides by serum. We found that combinations of these novel pantetheinase inhibitors and prototypic pantothenamides like N5-Pan and N7-Pan exerted antimicrobial activity in vitro, particularly against Gram-positive bacteria (Staphylococcus aureus, Staphylococcus epidermidis, Streptococcus pneumoniae, and Streptococcus pyogenes) even in the presence of serum. These results indicate that pantothenamides, when protected against degradation by host pantetheinases, are potentially useful antimicrobial agents.
shown to possess pantehtinase activity by the hydrolysis of pantehtiene into pantothenic acid (vitamin B5) and the low-molecular-weight thiol cysteamine (15). We found vanin family members to be broadly expressed in nearly all human tissues (16). On the basis of sequence similarities, vanins were classified as members of the biotinidase branch of the nitrilase superfamily (17). The most obvious function of biotinidases and pantethinases is that of amidases involved in vitamin recycling.

In the present paper, we address the possible application of pantethinamides as antibiotics, considering the current knowledge on human pantethinases. Based on the fact that vanins are active on the carbon-nitrogen bond of pantethiene, we hypothesized that antibiotic pantethinamides could also be hydrolyzed by pantethinase activity, which was indeed found to be the case. We further show that inhibition of pantethinase activity by novel chemotypes that we recently developed (18) protects pantethinamides against hydrolysis and preserves their antibiotic activity. We hereby provide proof of concept that combination of pantethinase inhibitors with pantethinamides might be a novel antimicrobial strategy.

MATERIALS AND METHODS

Bacterial growth assays. Strains of Escherichia coli, Staphylococcus aureus, Staphylococcus epidermidis, Streptococcus agalactiae, Streptococcus pyogenes, Klebsiella pneumoniae and Pseudomonas aeruginosa were grown overnight in 1% Bacto tryptone medium (BD, Sparks, MD). Cultures were then diluted 1:1,000 in fresh assay medium supplemented with or without 20% fetal bovine serum (FBS; HyClone, Célbio, Logan, UT) or 20% decomplemented human serum (Sanquin Blood Bank, The Netherlands) and added to 96-well sterile enzyme-linked immunosorbent assay (ELISA) plates (100 μl per well). Moraxella catarrhalis was grown on blood agar plates, and colonies were swabbed into in 1% Bacto tryptone medium and diluted to an optical density of 600 nm (OD 600) of 0.10. Subsequently, 100 μl was added to 96-well sterile ELISA plates. The compounds to be tested were diluted in the medium without serum and added to the bacteria (100 μl per well). Plates were incubated at 37°C, and bacterial growth was monitored over time by reading the optical density at 490 nm using a microplate reader (model 450; Bio-Rad Laboratories Inc., Hercules, CA). Streptococcus pneumoniae strains were grown to mid-log phase (OD600 = 0.3) and stored in 15% glycerol at −80°C till further use. Bacteria were diluted 10-fold in Mueller-Hinton medium (BD, Sparks, MD) and added to 96-well sterile ELISA plates (150 μl per well). The compounds to be tested were diluted in the medium without serum and added to the bacteria (150 μl per well). Plates were incubated overnight at 37°C in 5% CO2. The MIC was defined as the lowest concentration of pantethinamide or pantetheinase inhibitor. Over time, samples were taken, and the reaction was terminated by addition of 180 μl 100 mM CaCO3 (pH 10.5). Fluorescence was measured using a luminescence spectrometer (LS55; excitation wavelength, 350 ± 2.5 nm; emission wavelength, 450 ± 2.5 nm; PerkinElmer) against samples without serum as negative controls.

For mass-spectrometric analysis, 64 μg/ml N7-Pan was incubated for 24 h at room temperature with 1% fetal bovine serum diluted in phosphate buffer (500 μM phosphate potassium phosphate buffer, pH 8.0) with and without the addition of 256 μg/ml RR6.

Mass spectrometry analysis. Mass spectrometry was performed on a JEOL JMS-T100CS spectrometer (AccuTOF CS) connected to a Agilent 1100 series high-performance liquid chromatography (HPLC) system. Analysis was performed in infusion mode; 3 μl of sample (1% sample in methanol; HPLC grade; Fisher Scientific) was injected into a stream of methanol (HPLC grade; Fisher Scientific) containing 0.1% formic acid (puriss. p.a. for mass spectrometry; Fluka) and 50 nM PPG425 (polypropylene glycol; average molecular weight, 425; Sigma-Aldrich Chemie GmbH) for use as an internal mass drift compensator. Total analysis time with a flow rate of 100 μl/min was 2.5 min per sample. Sample information elutes between 0.3 and 1.0 min. Data between 0 and 0.3 min were used to mass drift compensate the calibration against PPG425 peaks, resulting in a mass precision better than 2 ppm.

In vitro toxicity. Human embryonic kidney 293T cells were grown in Dulbecco’s modified Eagle medium (DMEM-Glutamax; Gibco Invitrogen) containing 10% FBS (HyClone, Célbio, Logan, UT), 100 μg/ml penicillin-streptomycin, and 1% pyruvate (Gibco Invitrogen) at 37°C and 5% CO2. Pantethinamide or pantetheinase inhibitors were added to these cultures for 48 h, and the effects on growth and toxicity were determined microscopically. Cytotoxicity was detected using the LDH cytototoxicity detection kit according to the manufacturer’s protocol (Roche Applied Science, Indianapolis, IN). A rate of cell death of 100% was determined after addition of 1% Triton X-100 to the cells.

Statistics. Data were analyzed using GraphPad Prism version 5. Data are expressed as means ± standard deviations.

FIG 1 Effect of serum on pantethinamides. The growth-inhibiting effect of N5-Pan on E. coli in media containing increasing amounts of serum was assessed. In serum-free medium, a low concentration of N5-Pan is sufficient to inhibit bacterial growth, while in a 1% serum medium, a high concentration N5-Pan is needed for bacterial growth inhibition. In 10% serum, a high concentration of N5-Pan is insufficient to act as an antibiotic, n = 4 for all samples.
Pantothenamides are inactive as antibiotics in serum-containing medium. To test whether pantothenamides have antibiotic activity under physiological conditions, *E. coli* was cultured in minimal medium in the presence of complement-inactivated serum (in this case, fetal bovine serum, but human serum gives similar results). Addition of the prototypic pantothenamide N5-Pan to log-phase cultures of *E. coli* in the absence of serum shows the expected growth-inhibiting properties as described before (2) (Fig. 1). Addition of 1% and 10% serum dose-dependently abolishes the inhibitory effect of N5-Pan.

We next investigated if the effect of serum on pantothenamides was due to a heat-labile factor. Figure 2A shows that heat-inactivated serum (5 min at 100°C) is unable to interfere with N5-Pan-mediated growth inhibition of *E. coli*. This made it very likely that the effect was due to one or more proteins present in serum.

Pantothenamides are hydrolyzed in serum. Based on structural homology of pantothenamides with pantetheine and the knowledge that pantetheine is hydrolyzed by pantetheinases of the vanin family into pantothenic acid and cysteamine, we hypothesized that this class of enzymes could also hydrolyze pantothenamides. In a previous study, we showed that vanins are ubiquitously expressed (16). Using an aminomethylcoumarine derivative of pantothenic acid, which is a pantothenamide with a fluorescent leaving group as a substrate (19), pantetheinase activity in serum is readily detected. We found that this hydrolytic activity was completely abolished by heat inactivation of the serum (Fig. 2B).

Subsequently, we investigated whether known antibiotic pantothenamides are also hydrolyzed in the presence of serum. Mass-spectrometric analysis of N7-Pan incubated in 1% serum for 24 h revealed a complete disappearance of the N7-Pan peak, whereas a clear peak of heptylamide, the expected hydrolysis product, appears (Fig. 3A). This indicates that pantothenamides are indeed hydrolyzed in the presence of serum.

Pantetheinase inhibitors prevent degradation of antibiotic pantothenamides in serum. We reasoned that inhibitors of serum pantetheinases could prevent degradation of pantothenamides in biological fluids, thereby preserving their antibiotic activity. As there were no selective high-affinity (subnanomolar) pantetheinase inhibitors available, we designed and synthesized a number of new inhibitors starting from pantetheine, the natural substrate of pantetheinases, as a scaffold. A description of the synthesis and characterization of these new chemotypes, pantetheine analogs lacking the hydrolysable amide bond, has recently been published (18). The most potent and selective inhibitor (RR6) showed a 50% inhibitory concentration (IC50) of 40 nM against pantetheinase activity present in human or bovine serum. See Table S1 in the supplemental material for the structures and IC50s of all compounds used here.

We next investigated if these pantetheinase inhibitors could protect pantothenamide antibiotics from hydrolysis by serum pantetheinase activity. Figure 3B shows the results of mass spectrometric analysis of N7-Pan incubated in 1% serum for 24 h in the presence of 256 μg/ml RR6. Whereas in Fig. 3A, a complete disappearance of the N7-Pan peaks is observed and only the hydrolysis product heptylamine can be identified, Fig. 3B shows that in the presence of RR6, the N7-Pan peaks are still present. Although we found a minor peak corresponding to heptylamide, we conclude that N7-Pan is clearly protected against hydrolysis by the addition of a pantetheinase inhibitor.

**RESULTS**

Pantothenamides are inactive as antibiotics in serum-containing medium. To test whether pantothenamides have antibiotic activity under physiological conditions, *E. coli* was cultured in minimal medium in the presence of complement-inactivated serum (in this case, fetal bovine serum, but human serum gives similar results). Addition of the prototypic pantothenamide N5-Pan to log-phase cultures of *E. coli* in the absence of serum shows the expected growth-inhibiting properties as described before (2) (Fig. 1). Addition of 1% and 10% serum dose-dependently abolishes the inhibitory effect of N5-Pan.

We next investigated if the effect of serum on pantothenamides was due to a heat-labile factor. Figure 2A shows that heat-inactivated serum (5 min at 100°C) is unable to interfere with N5-Pan-mediated growth inhibition of *E. coli*. This made it very likely that the effect was due to one or more proteins present in serum.

Pantothenamides are hydrolyzed in serum. Based on structural homology of pantothenamides with pantetheine and the knowledge that pantetheine is hydrolyzed by pantetheinases of the vanin family into pantothenic acid and cysteamine, we hypothesized that this class of enzymes could also hydrolyze pantothenamides. In a previous study, we showed that vanins are ubiquitously expressed (16). Using an aminomethylcoumarine derivative of pantothenic acid, which is a pantothenamide with a fluorescent leaving group as a substrate (19), pantetheinase activity in serum is readily detected. We found that this hydrolytic activity was completely abolished by heat inactivation of the serum (Fig. 2B).

Subsequently, we investigated whether known antibiotic pantothenamides are also hydrolyzed in the presence of serum. Mass-spectrometric analysis of N7-Pan incubated in 1% serum for 24 h revealed a complete disappearance of the N7-Pan peak, whereas a clear peak of heptylamide, the expected hydrolysis product, appears (Fig. 3A). This indicates that pantothenamides are indeed hydrolyzed in the presence of serum.

Pantetheinase inhibitors prevent degradation of antibiotic pantothenamides in serum. We reasoned that inhibitors of serum pantetheinases could prevent degradation of pantothenamides in biological fluids, thereby preserving their antibiotic activity. As there were no selective high-affinity (subnanomolar) pantetheinase inhibitors available, we designed and synthesized a number of new inhibitors starting from pantetheine, the natural substrate of pantetheinases, as a scaffold. A description of the synthesis and characterization of these new chemotypes, pantetheine analogs lacking the hydrolysable amide bond, has recently been published (18). The most potent and selective inhibitor (RR6) showed a 50% inhibitory concentration (IC50) of 40 nM against pantetheinase activity present in human or bovine serum. See Table S1 in the supplemental material for the structures and IC50s of all compounds used here.

We next investigated if these pantetheinase inhibitors could protect pantothenamide antibiotics from hydrolysis by serum pantetheinase activity. Figure 3B shows the results of mass spectrometric analysis of N7-Pan incubated in 1% serum for 24 h in the presence of 256 μg/ml RR6. Whereas in Fig. 3A, a complete disappearance of the N7-Pan peaks is observed and only the hydrolysis product heptylamine can be identified, Fig. 3B shows that in the presence of RR6, the N7-Pan peaks are still present. Although we found a minor peak corresponding to heptylamide, we conclude that N7-Pan is clearly protected against hydrolysis by the addition of a pantetheinase inhibitor.

**In vitro antibiotic effects of combinations of pantothenamides and pantetheinase inhibitors.** We next examined if inhibition of serum pantetheinase could preserve the antibiotic effect

**FIG 2** Inactivation of N5-Pan by serum is due to a heat-labile factor. (A) N5-Pan (64 μg/ml) (filled bars) does not inhibit growth of *E. coli* in the presence of FBS. Upon heat inactivation of serum (5 min at 100°C), N5-Pan effectively inhibits bacterial growth. Open bars, bacterial growth without N5-Pan. *n* = 4 for all samples. (B) A pantetheinase activity assay showed pantetheinase activity in serum (×) but none in inactivated serum (+), confirming that pantetheinases might be involved in pantothenamide inactivation.

**FIG 3** Hydrolysis of N7-Pan is inhibited RR6. (A) Mass spectrometric analysis of a sample containing 1% serum and N7-Pan after 24 h incubation showed a heptylamine peak but no N7-Pan peak. Note that the produced pantothenic acid is only partially visualized with the settings used. (B) Pantetheinase inhibitor RR6 is able to protect N7-Pan against hydrolysis, as clear peaks corresponding to the N7-Pan adducts are shown on the mass spectrum. Also, the RR6 adducts and a very small peak corresponding to heptylamine were detected. The reaction was performed as described for panel A.
of the pantothenamides N5-Pan and N7-Pan, which were previously reported to be active against strains of *E. coli* and *S. aureus*, respectively. Figure 4 shows the effects of pantothenamides or a pantetheinase inhibitor (RR6) alone and combinations of these. The addition of pantothenamides had no antibacterial effect in medium with 10% FBS, as shown before for N5-Pan (Fig. 1). Similarly, the pantetheinase inhibitor RR6 on its own did not affect growth of *E. coli* or *S. aureus*. Combination of RR6 with pan-
tothenamides, however, showed a clear antimicrobial effect for N5-Pan on *E. coli* (Fig. 4A) and for N7-Pan on *S. aureus* (Fig. 4B). We performed checkerboard titration of pantothenamides and the pantetheinase inhibitor RR6 to obtain a range of MICs for the combined compounds, as shown in Fig. 4C. The protective effect of RR6 toward pantothenamides is clearly visible for both *E. coli* and *S. aureus*. The amount of pantothenamides decreased to MIC values in cultures without serum and RR6 (Fig. 4D).

**Specificity and toxicity of pantothenamide antibiotics and vanin inhibitors.** The efficacy of pantothenamides has so far been studied only *in vitro* on a limited number of bacterial species (2, 11). To delineate the taxa that are potential targets for antibiotic therapy, we determined the MIC values for a number of clinically relevant species. Table 1 shows that only Gram-positive bacteria are sensitive to pantothenamides at pharmacologically realistic concentrations (8 µg/ml). Sensitive species include *S. aureus*, *S. pneumoniae*, *S. pyogenes*, and *S. epidermidis*. Within one genus (streptococci), there is differential sensitivity, as *S. agalactiae* is resistant, in contrast to *S. pyogenes* and *S. pneumoniae*. We tested several strains of selected species for confirmation (see Table S2 in the supplemental material).

As the putative mode of action of pantothenamides is at the level of CoA-dependent biochemical pathways, this raised the question of selectivity for microbial versus host targets. We therefore investigated if pantothenamides and pantetheinase inhibitors were tolerated by mammalian cells. Using concentrations of N5-Pan, N7-Pan, and RR6 up to 2,000 µM, no effects on cell growth or viability were observed in a human cell line (293T kidney cells) (Fig. 5). Similar results were found on primary human keratinocytes (data not shown).

**DISCUSSION**

Here we provide detailed experimental evidence for the concept that pantetheinase inhibitors can prevent the enzymatic degradation of pantothenamide antibiotics. Combination of a pantetheinase inhibitor with pantothenamides could be a successful strategy to preserve the antibiotic properties of pantothenamides in the presence of host pantetheinases. We propose that our data provide proof of concept for a novel antibiotic strategy that could be used against clinically relevant Gram-positive bacteria.

Since pantothenic acid was first described as a nutritional requirement for most if not all organisms, its potential for antibiotic drug design has been investigated. The different mechanisms by which organisms were able to obtain pantothenic acid for CoA biosynthesis and the relatively low homology between enzymes involved in pantothenic acid processing opened the field to design growth-inhibiting molecules specific for pathogens. Based on pantothenic acid, different classes of molecules were described to possess anti-bacterial, anti-fungal, and anti-parasitic activities *in vitro*, including N-pantoyl-substituted amines, pantoylhydrazides, pantothiones, and pantothenamides (20). Most of these analogues were expected to compete with endogenous pantothenic acid for the first enzyme of the CoA biosynthesis, CoA. In contrast, the working mechanism of pantothenamides is expected to be different. Strauss and Begley (10) showed that N-pentylpantothenamide is a substrate for CoA rather than an inhibitor. They showed that the pantetheinase is completely processed to a CoA analogue called ethylidethia-CoA and that the conversion is over 10 times faster than pantothenic acid processing. Subsequently, Zhang et al. showed that acyl carrier protein (ACP) is the cellular target, which results in an inactive ACP analogue that lacks the sulphydryl group for the attachment of acyl chains for fatty acid synthesis (3). Mercer et al. have shown that pantothamide azido-pantetheine could be processed to ACP via FAS type II in bacteria, while it cannot be processed via FAS type I in the human cell line SKBR3 (21). Apparently, CoA analogues are recognized only by type II fatty acid synthase, which is found in most bacteria, while a FAS type I system is present in mammals and fungi. Because the structural arrangements of fungal and mammalian synthases differ, selective pantothanes could theoretically also target fungal FAS type I. Assuming that pantothanes target the bacterial FASII pathway, administration of exogenous fatty acids could potentially overcome the antibiotic effects of pantothenamides. Work by Zhang et al. showed that this is not the case for *E. coli*. The MIC for *S. pneumoniae*, however, was increased

![Fig 5 In vitro toxicity of compounds. Cytotoxicity was measured on human embryonic kidney 293T cells treated with or without N5-Pan, N7-Pan, or RR6. None of the tested compounds or combination resulted in increased cell death up to 2,000 µM. Triton X-100 (1%) was added to cells to achieve 100% cytotoxicity.](image-url)
achieve complete protection of pantothenamides in serum and to potency of our current vanin inhibitors needs to be improved to tors can enter drug development. As witnessed by Fig. 4C, the nation therapy of pantothenamide antibiotics and vanin inhibi-
dium falciparum. (5).

The first step in CoA biosynthesis is the phosphorylation of pantothenic acid by pantothenate kinase (PanK), the key regulatory enzyme that is subject to self-regulation through feedback inhibition by CoA. Structures of PanK enzymes among different species have been investigated and showed differences in binding capacity for pantothenic acid (23, 24). This might explain why N5-Pan is more active against E. coli and N7-Pan has specificity for S. aureus. Binding features of human PanK family members with pantothenic acid have not been investigated. Although structures of human PanK1α and PanK3 in complex with acetyl-CoA have been analyzed, the structure of human PanK isoforms in complex with pantothenic acid would further facilitate the knowledge of binding properties of PanK and thus would provide more insight into possible modifications of pantothenic acid to aid medicinal chemistry efforts.

We have no data on whether our panteinase inhibitors are PanK substrates. We have shown that panteinase inhibitors by themselves are not antibiotic, which suggests that they are not a substrate for the CoA biosynthetic machinery. This may be caused by the loss of the amide bond, which is likely to be a structural requirement for entering the first step of CoA synthesis leading to CoA antimetabolites, as recently suggested in a study by Mercer et al. (5).

A recent publication identified panteinase inhibitors derived from various chemical scaffolds in the LOPAC library, via a high-throughput approach (19). These compounds are all nonselective and have modest potency. As they are known to target various mammalian cellular pathways at concentrations that are lower than required for vanin inhibition, it is unlikely that these compounds are useful in pharmacology or biological chemistry approaches (25, 26).

The antibiotic strategy described here includes a combination of an enzyme inhibitor and a molecule that interferes with bacte-
rial growth. Although a dual-compound formulation is not a preferred pharmaceutical approach, it is not unprecedented, as wit-
essed by the use of beta-lactamase inhibitors (combined with penicillin) and a dehydropeptidase inhibitor (combined with imi-
penem) (27). Here, we provide detailed experimental data for a concept that we previously put forward (28, 29). Recently, indirect evidence supporting this concept was found in the case of Plasmodium falciparum growth inhibition by pantothenamides (30).

Obviously, a number of steps need to be taken before combination therapy of pantothenamide antibiotics and vanin inhibi-
tors can enter drug development. As witnessed by Fig. 4C, the potency of our current vanin inhibitors needs to be improved to achieve complete protection of pantothenamides in serum and to maintain the required MIC values (31) (e.g., around 1 μg/ml for S. aureus). We found a good bioavailability and pharmacodynamic profile of the vanin inhibitor RR6 (18), which is encouraging for further exploration of this possibility. Clearly, an increase of the potency of current pantothenamides (N5-Pan and N7-Pan) is required. If this can be achieved, their application and sensitivity may even extend beyond the Gram-positive species that we have identified here.
