Search for flavour-changing neutral current top-quark decays to $qZ$ in $pp$ collision data collected with the ATLAS detector at $\sqrt{s} = 8$ TeV

The ATLAS Collaboration

Abstract

A search for the flavour-changing neutral-current decay $t \rightarrow qZ$ is presented. Data collected by the ATLAS detector during 2012 from proton–proton collisions at the Large Hadron Collider at a centre-of-mass energy of $\sqrt{s} = 8$ TeV, corresponding to an integrated luminosity of 20.3 fb$^{-1}$, are analysed. Top-quark pair-production events with one top quark decaying through the $t \rightarrow qZ$ ($q = u, c$) channel and the other through the dominant Standard Model mode $t \rightarrow bW$ are considered as signal. Only the decays of the $Z$ boson to charged leptons and leptonic $W$ boson decays are used. No evidence for a signal is found and an observed (expected) upper limit on the $t \rightarrow qZ$ branching ratio of $7 \times 10^{-4} (8 \times 10^{-4})$ is set at the 95% confidence level.
1 Introduction

The top quark is the heaviest elementary particle known, with a mass \( m_t = 173.21 \pm 0.51 \text{(stat.)} \pm 0.71 \text{(syst.)} \) GeV \[1\]. Its lifetime is so short that, within the Standard Model (SM) of particle physics, it decays (almost exclusively to \( bW \)) before hadronisation occurs. These properties make it a particle well suited to test the predictions of the SM. In the SM, due to the GIM mechanism \[2\], flavour-changing neutral current (FCNC) decays such as \( t \to qZ \) are forbidden at tree level. They are allowed at one-loop level, but with a suppression factor of several orders of magnitude with respect to the dominant decay mode \[3\]. However, several SM extensions predict higher branching ratios (BRs) for the top-quark FCNC decays. Examples of such extensions are the quark-singlet model (QS) \[4\], the two-Higgs-doublet model with (FC 2HDM) or without (2HDM) flavour conservation \[5\], the minimal supersymmetric model (MSSM) \[6\], supersymmetry with R-parity violation (\( R \) SUSY) \[7\] or models with warped extra dimensions (RS) \[8\].

For a review see Ref. \[9\]. The maximum values for the \( t \to qZ \) BRs predicted by these models and by the SM are summarised in Table 1. Experimental limits on the FCNC \( t \to qZ \) BR were established by experiments at the Large Electron Positron Collider (LEP) \[10–14\], HERA \[15\], Tevatron \[16, 17\] and Large Hadron Collider (LHC) \[18, 19\]. The most stringent limit, \( \text{BR}(t \to qZ) < 5 \times 10^{-4} \), is the one from the CMS Collaboration \[19\] using 25 fb\(^{-1}\) of data collected at \( \sqrt{s} = 7 \) TeV and \( \sqrt{s} = 8 \) TeV. Previous ATLAS results obtained at \( \sqrt{s} = 7 \) TeV are also reported \[18\]. Limits on other FCNC top-quark decay BRs (\( t \to qX, X = \gamma, g, H \)) are reported in Refs. \[10–14, 20–28\].

This paper presents the ATLAS results from the search for the FCNC decay \( t \to qZ \) in \( \bar{t}t \) events produced at \( \sqrt{s} = 8 \) TeV, with one top quark decaying through the FCNC mode and the other through the SM dominant mode (\( t \to bW \)). Only the decays of the Z boson to charged leptons and leptonic W boson decays are considered. The final-state topology is thus characterised by the presence of three isolated charged leptons, at least two jets, and missing transverse momentum from the undetected neutrino. The paper is organised as follows. A brief description of the ATLAS detector is given in Section 2. The collected data samples and the simulations of signal and SM background processes are described in Section 3. Section 4 presents the object definitions, while the event analysis and kinematic reconstruction are explained in Section 5. Background evaluation and sources of systematic uncertainty are described in Sections 6 and 7. Results are presented in Section 8 and conclusions are drawn in Section 9.

2 Detector and data samples

The ATLAS experiment is a multi-purpose particle physics detector consisting of several sub-detector systems, which cover almost fully the solid angle\(^1\) around the interaction point. It is composed of an inner tracking system close to the interaction point and immersed in a 2 T axial magnetic field produced by a thin superconducting solenoid, a lead/liquid-argon (LAr) electromagnetic calorimeter, an iron/scintillator-tile hadronic calorimeter, copper/LAr hadronic endcap calorimeter and a muon spectrometer with three superconducting magnets, each one with eight toroid coils. The forward region is covered by additional LAr calorimeters with copper and tungsten absorbers. The combination of all these systems provides

\(^1\) ATLAS uses a right-handed coordinate system with its origin at the nominal interaction point in the centre of the detector and the z-axis along the beam pipe. The x-axis points from the interaction point to the centre of the LHC ring, and the y-axis points upward. Cylindrical coordinates \((r, \phi)\) are used in the transverse plane, \(\phi\) being the azimuthal angle around the beam pipe. The pseudorapidity is defined in terms of the polar angle \(\theta\) as \(\eta = -\ln \tan(\theta/2)\). The \(\Delta R\) distance is defined as \(\Delta R = \sqrt{(\Delta \eta)^2 + (\Delta \phi)^2}\).
charged-particle momentum measurements, together with efficient and precise lepton and photon identification in the pseudorapidity range $|\eta| < 2.5$. Energy deposits over the full coverage of the calorimeters, $|\eta| < 4.9$ are used to reconstruct jets and missing transverse momentum (with magnitude $E_T^{\text{miss}}$). A three-level trigger system is used to select interesting events. The Level-1 trigger is implemented in hardware and uses a subset of detector information to reduce the event rate to a design value of at most 75 kHz. This is followed by two software-based trigger levels which together reduce the event rate to less than 1 kHz. A detailed description of the ATLAS detector is provided in Ref. [29].

In this paper the full 2012 dataset from proton–proton ($pp$) collisions at $\sqrt{s} = 8$ TeV is used. The analysed events were recorded by single-electron or single-muon triggers and fulfil standard data-quality requirements. Triggers with different transverse momentum thresholds are used to increase the overall efficiency. The triggers using a low transverse momentum ($p_T$) threshold ($p_T^{e,\mu} > 24$ GeV) also have an isolation requirement. Efficiency losses at higher $p_T$ values are recovered by higher threshold triggers ($p_T^{e} > 60$ GeV or $p_T^{\mu} > 36$ GeV) without any isolation requirement. The integrated luminosity of the analysed data sample is 20.3 fb$^{-1}$.

### 3 Simulated samples

In the SM, top quarks are produced at the LHC mainly in pairs, with a predicted $t\bar{t}$ cross section in $pp$ collisions at a centre-of-mass energy of $\sqrt{s} = 8$ TeV of $\sigma_{t\bar{t}} = 253^{+13}_{-15}$ pb for a top-quark mass of 172.5 GeV. The cross section has been calculated at next-to-next-to leading-order (NNLO) in QCD including resummation of next-to-next-to leading logarithmic (NNLL) soft gluon terms with Top++ 2.0 [30–35]. The parton distribution function (PDF) and $\alpha_S$ uncertainties are calculated using the PDF4LHC prescription [36] with the MSTW 2008 68% CL NNLO [37, 38], CT10 NNLO [39, 40] and NNPDF 2.3 5f FFN [41] PDF sets and are added in quadrature to the renormalisation and factorisation scale uncertainties. The cross-section value for the NNLO+NNLL calculation is about 3% larger than the exact NNLO prediction implemented in HATHOR 1.5 [42].

The simulation of signal events is performed with PROTON 2.2 [43, 44], which includes the effects of new physics at an energy scale $\Lambda$ by adding dimension-six effective terms to the SM Lagrangian. The most general $Ztu$ vertex that arises from the dimension-six operators can be parameterised including only $\gamma^\mu$ and $\sigma^{\mu\nu}q_\nu$ terms [45] as:

$$L_{Ztu} = -\frac{g}{2c_W} i \bar{u} \gamma^\mu \left( X^{L}_L P_L + X^{R}_R P_R \right) t Z_\mu - \frac{g}{2c_W} i \sigma^{\mu\nu} q_\nu \left( X^{L}_L P_L + X^{R}_R P_R \right) t Z_\mu + \text{h.c.},$$

where $g$ is the electroweak coupling, $c_W$ is the cosine of the weak mixing angle, $u$ and $t$ are the quark spinors, $Z_\mu$ is the Z boson field, $P_L$ ($P_R$) is the left-handed (right-handed) projection operator, $m_Z$ is the Z

boson mass and \( q^{T} = p_{T}^{e} - p_{T}^{\mu} \) is the outgoing Z boson momentum. The \( Zt \) vertex can be parameterised in a similar fashion. This vertex involves a minimum of four anomalous couplings \( \kappa_{\mu}, \kappa_{\mu}, \kappa_{\mu}, \kappa_{\mu} \) which are set to 0.01 each. It was checked that the coupling choice does not affect the kinematics of the event. No impact in the kinematics is seen by comparing the \( bbW\nuZ \) and \( bWc\nuZ \) processes and the latter is used as reference. Only decays of the \( W \) and \( Z \) bosons involving charged leptons are generated at the matrix-element level by PROTOS (\( Z \rightarrow e^{+}e^{-}, \mu^{+}\mu^{-}, \tau^{+}\tau^{-} \) and \( W \rightarrow e\nu, \mu\nu, \tau\nu \)). The CTEQ6L1 [46] leading-order PDF is used. To account for higher-order contributions in the signal production, the events are reweighted to the measured \( \bar{t}\bar{t} \) differential cross section as a function of the transverse momentum of the \( t\bar{t} \) system \((1/\sigma)(d\sigma/dp_{T}^{\ell}) \) [47]. Hadronisation is handled by PYTHIA 6.426 [48] with the Perugia2011C [49] set of tuned parameters and \( \tau \) decays are processed with TAUOLA [50]. The top-quark mass is set to \( m_{t} = 172.5 \) GeV. Additional simulations with different parton shower parameterisations are used to estimate the systematic uncertainties on the amount of initial- and final-state radiation (ISR/FSR).

Several SM processes have final-state topologies similar to the signal, with at least three prompt charged leptons, especially \( WZ, ZZ, t\bar{t}V, t\bar{t}H, ggH, VH, t\bar{z} \) and trisboson \((WWW, ZWW \text{ and } ZZZ) \) production. Events with non-prompt leptons or in which at least one jet is misidentified as an isolated charged lepton (labelled as “fake leptons” throughout this paper) can also fulfil the event selection requirements. These events, typically \( Z+\nu, Z+\gamma, t\bar{t} \) and single-top, are estimated from a data-driven method using a parameterisation of the true- and fake-lepton efficiencies. Samples of simulated events of these backgrounds with fake leptons are used to cross-check the data-driven estimation. The \( Z+\nu \) simulations include \( Z \) production in association with heavy-flavour quarks.

Table 2 summarises the information about the generators, parton shower and parton distribution functions used to simulate the different event samples considered in the analysis. Diboson events \((WZ \text{ and } ZZ) \) are generated at the matrix-element level by PROTOS, produced with SHERPA contain up to three additional partons and are selected to have leptons with \( p_{T} > 5 \) GeV and \( m_{tt} > 0.1 \) GeV for the \( Z/\gamma^{*} \). The additional \( WZ \) and \( ZZ \) samples are used for comparison. The \( WZ \) ALPGEN samples are simulated with up to five additional partons from the matrix element. The \( ZZ \) HERWIG [51] samples are selected to have one lepton with \( p_{T} > 10 \) GeV and \( |\eta| < 2.8 \). The simulations of \( t\bar{t}Z, t\bar{t}W(W), t\bar{z} \) and trisboson include events with up to two extra partons in the final state. The simulated samples used to cross-check the data-driven estimation of background with fake leptons are also listed in Table 2.

Detailed and fast simulations of the detector and trigger are performed with standard ATLAS software using GEANT4 [52, 53] and ATLFASTII [53], respectively. The same offline reconstruction methods used on data are applied to the simulated samples.

4 Object reconstruction

The primary physics objects considered in this search are electrons, muons, \( E_{T}^{\text{miss}} \), jets, and \( b \)-tagged jets. Tau leptons are not explicitly reconstructed, although the \( \tau \) decay products are reconstructed as electrons, muons or jets and as an additional contribution to the missing transverse momentum.

Electron candidates are reconstructed [63] from energy deposits (clusters) in the electromagnetic calorimeter, which are then matched to reconstructed charged-particle tracks in the inner detector. The candidates are required to have a transverse energy \( E_{T} \) greater than 15 GeV and a pseudorapidity of the calorimeter cluster associated with the electron candidate \( |\eta_{\text{cluster}}| < 2.47 \). Candidates in the transition

Region between the barrel and endcap calorimeters with \( 1.37 < |\eta_{\text{cluster}}| < 1.52 \) are excluded. Electron candidates in this analysis must satisfy tight quality requirements on the electromagnetic cluster and associated track which provide discrimination between isolated electrons and jets. In order to suppress multi-jet backgrounds, it is also required that there is little activity in the space surrounding the electron. Two isolation variables are employed: the energy deposited around the electron in the calorimeter in a cone of size \( \Delta R = 0.2 \) and the scalar sum of the \( p_T \) of the tracks within cone of size \( \Delta R = 0.3 \) around the electron. Cuts on these two quantities are used to select isolated electrons; the adopted cuts yield a 90% identification efficiency in Z boson decays to e+e− events from the full 2012 dataset. Additionally, the longitudinal impact parameter \( |z_0| \) of the electron track with respect to the selected primary vertex of the event is required to be less than 2 mm. The closest jet if separated by \( \Delta R < 0.2 \) from the selected electron is removed from the event. The electron candidate is discarded if an additional selected jet is found with \( \Delta R < 0.4 \). A looser electron selection, used for the estimation of backgrounds with fake leptons, is defined by removing the isolation requirements.

The muon candidate reconstruction [64] is performed by finding, combining and fitting track segments in the layers of the muon chambers, starting from the outermost layer. The identified muons are then matched with tracks reconstructed in the inner detector. The candidates are refit using the complete track information from both detector systems, and are required to satisfy \( p_T > 15 \text{ GeV}, |\eta| < 2.5 \) and to be separated by \( \Delta R > 0.4 \) from any selected jet. The hit pattern in the inner detector is required to be consistent with a well-reconstructed track and the \( |z_0| \) of the muon track is required to be less than 2 mm. Additionally, the sum of the momenta of tracks inside a cone around the muon candidate, with variable size such that it is smaller for higher muon \( p_T \) [65], must be less than 5% of the muon energy. For the estimation of backgrounds with fake leptons, a looser selection is applied by removing the isolation requirement.

Jets are reconstructed [66] from topological clusters of neighbouring calorimeter cells with significant
energy deposits using the anti-
Kt algorithm \[67\] with a radius parameter \(R = 0.4\). Prior to jet finding, a
local calibration scheme is applied to correct the topological cluster energies for the non-compensating
response of the calorimeter, dead material and energy leakage. The corrections are obtained from simu-
lations of charged and neutral particles. These jets are then calibrated to the hadronic energy scale using
\(p_T\)- and \(\eta\)-dependent correction factors. Dedicated requirements are applied to remove the negligible
fraction of events (less than 0.01\%) where a jet is incorrectly reconstructed from a few noisy calorimeter
cells \[68\]. The jets used in the analysis are required to have \(p_T > 25\) GeV and \(|\eta| < 2.5\). To reduce the
number of selected jets that originate from secondary \(p\bar{p}\) interactions, for jets with \(p_T < 50\) GeV and
\(|\eta| < 2.4\), the scalar sum of the \(p_T\) of tracks matched to a jet and originating from the primary vertex must
be at least 50\% of the scalar sum of the \(p_T\) of all tracks matched to the jet.

Jets containing \(b\)-hadrons are identified (‘\(b\)-tagged’) \[69\] using an algorithm based on multivariate tech-
niques. It combines information from the impact parameters of displaced tracks and from topological
properties of secondary and tertiary decay vertices reconstructed within the jet. It is determined with
simulated \(t\bar{t}\) events that, for the chosen working point, the tagging efficiency for \(b\)-jets with \(p_T > 20\) GeV
is 70\%, while the rejection factors for light-quark or gluon jets (light jets), charm jets and \(\tau\) leptons are
137, 5 and 13, respectively.

The measurement of \(E_{\text{T}}^{\text{miss}}\) is based \[70\] on the energy deposits in the calorimeter with \(|\eta| < 4.9\). The en-
ergy deposits associated with reconstructed jets and electrons are calibrated accordingly. Energy deposits
not associated with a reconstructed object are calibrated according to their energy sharing between the
electromagnetic and hadronic calorimeters. The momentum associated with each reconstructed muon,
estimated using the momentum measurement of its reconstructed track, is taken into account in the cal-
culation of \(E_{\text{T}}^{\text{miss}}\).

## 5 Event selection and kinematics

At least one of the selected leptons must be matched, with \(\Delta R < 0.15\) to the appropriate trigger object
and have \(p_T > 25\) GeV. The trigger efficiencies for the leptons are approximately 93\% for electrons, 70\% 
for muons with \(|\eta| < 1.05\) and 86\% for muons with \(1.05 < |\eta| < 2.4\) \[71, 72\]. The events are required to
have at least one primary vertex with more than four associated tracks, each with \(p_T > 400\) MeV. The
primary vertex is chosen as the one with the highest \(\sum p_T^2\) over all associated tracks. Leptons from cosmic
rays are rejected by removing muon pairs with large, oppositely signed transverse impact parameters
\(|d_0| > 0.5\) mm) and consistent with being back-to-back in the \(r - \phi\) plane. Events with noise bursts and
readout errors in the LAr calorimeter are also rejected. Exactly three isolated leptons associated with the
same vertex are required. The three leptons must have \(|\eta| < 2.5\) and \(p_T > 15\) GeV. Two of the leptons
are required to have the same flavour, opposite charge and a reconstructed mass within 15 GeV of the \(Z\)
boson mass \((m_Z)\) \[1\]. If more than one compatible lepton-pair is found, the one with the reconstructed
mass closest to \(m_Z\) is chosen as the \(Z\) boson candidate. According to the signal topology, the events
are then required to have \(E_{\text{T}}^{\text{miss}} > 20\) GeV and two jets, although an additional third jet from initial- or
final-state radiation is allowed. All jets are required to have \(p_T > 35\) GeV and \(|\eta| < 2.5\). One or two of
the jets must be \(b\)-tagged. Only one \(b\)-tagged jet is expected in the signal events, nevertheless a second
one can arise from a misidentified c-jet associated with the FCNC decay of the top quark. Allowing for
the additional \(b\)-tagged jet increases the signal efficiency without compromising the signal-to-background
ratio.
Applying energy–momentum conservation, the kinematics of the top quarks can be reconstructed from the corresponding decay particles. Since the neutrino from the semileptonic decay of the top quark ($t \to bW \to b\ell \nu$) is undetected, its four-momentum must be estimated. This can be done by assuming that the lepton not previously assigned to the Z boson and the $b$-tagged jet (labelled $b$-jet) originate from the $W$ boson and SM top-quark decays, respectively, and that $E_T^{\text{miss}}$ is the neutrino’s transverse momentum. The longitudinal component of the neutrino’s momentum ($p^z_\nu$) is then determined by minimising, without constraints, the following expression:

$$
\chi^2 = \frac{(m_{\text{reco}} - m_{\text{FCNC}})^2}{\sigma_{\text{FCNC}}^2} + \frac{(m_{\text{reco}} - m_{\text{SM}})^2}{\sigma_{\text{SM}}^2} + \frac{(m_{\text{reco}} - m_W)^2}{\sigma_W^2},
$$

(2)

where $m_{\text{reco}}$, $m_{\text{FCNC}}$, $m_{\text{SM}}$ and $m_W$ are the reconstructed masses of the $qZ$, $bW$ and $\ell\nu$ systems, respectively. The central value for the masses and the widths of the top quarks and $W$ boson are taken from reconstructed simulated signal events. This is done by matching the true particles in the simulated events to the reconstructed simulated signal events. For each jet combination, where any jet can be assigned to $j_a$, while $j_b$ must correspond to a $b$-tagged jet, the $\chi^2$ minimisation gives the most probable value for $p^z_\nu$. From all combinations, the one with the minimum $\chi^2$ is chosen, along with the corresponding $p^z_\nu$ value. The jet from the top-quark FCNC decay is referred to as the light-quark ($q$) jet. The fractions of correct assignments between the reconstructed top quarks and the true simulated neutrino and top quark and $W$ boson are taken from reconstructed simulated signal events. To study the $WZ$ background control region is defined by requiring three leptons, two of them with the same flavour, opposite charge, and a reconstructed mass within 15 GeV of the $Z$ boson mass. The expected and observed yields are shown in Table 3 and the SHERPA sample is chosen as reference.

The selection of the signal region is concluded with the requirement of $\chi^2 < 6$, which optimises the sensitivity discussed in Section 8.

6 Background estimates

Three control regions are defined to check the agreement between data and simulated samples of the ZZ, WZ and $t\bar{t}Z$ backgrounds. No scaling factors are derived from these control regions, however they are used to estimate the background modelling uncertainties described in Section 7. The $t\bar{t}Z$ contribution to the total background is expected to be smaller than the one from $t\bar{t}Z$ events [74]. Due to the similarity between the final states of $t\bar{t}Z$ and signal events, there are large signal contributions to possible $t\bar{t}Z$ control regions. For these reasons no control region is defined for the $t\bar{t}Z$ background.

The ZZ control region is defined by requiring two pairs of leptons with the same flavour, opposite charge and a reconstructed mass within 15 GeV of the $Z$ boson mass. The expected and observed yields are shown in Table 3 and the SHERPA sample is chosen as reference.
Figure 1: Expected (filled histogram) and observed (points with error bars) distributions in the signal region before the \( \chi^2 \) cut is applied for (a) \( p_T \) of the third lepton, (b) \( E_T^{\text{miss}} \) and (c) \( \chi^2 \) of the kinematics reconstruction. For comparison, distributions for the FCNC \( t \bar{t} \rightarrow bWqZ \) signal (dashed line), normalised to the observed 95\% CL limit reported in this paper, are also shown. Background statistical uncertainties associated with the number of events in the samples are represented by the hatched areas.

Table 3: Event yields in the ZZ control region for all significant sources of background. The ZZ SHERPA sample is taken as reference for the total background estimation. The first uncertainty is the statistical one associated with the number of events in the simulated samples, the second uncertainty is systematic and is described in Section 7. The entry labelled “other backgrounds” includes all the remaining backgrounds described in Section 3 and in Table 2. The signal efficiency is also shown.

\(p_T > 35\) GeV, no \(b\)-tagged jets with \(p_T > 35\) GeV and a W boson transverse mass, built with the residual lepton and \(E_T^{\text{miss}}\), greater than 50 GeV. Table 4 shows the expected and observed yields in this control region. The best estimation comes from the SHERPA prediction, which is chosen as the reference sample.

The \(t\bar{t}Z\) control region is defined by requiring at least three leptons, two of them with the same flavour, opposite charge and a reconstructed mass within 15 GeV of the Z boson mass. Furthermore the events are required to have at least two jets with \(p_T > 25\) GeV and at least two \(b\)-tagged jets if there are three leptons in the event, or at least one \(b\)-tagged jet if there are four or more leptons in the event. Since the signal contribution for events with three leptons and two \(b\)-tagged jets is small, the overlap between signal and background regions is not removed, increasing the \(t\bar{t}Z\) sensitivity in this control region. Table 5 shows the yields in this control region, and the background yields agree very well with the data within the given uncertainty.

Backgrounds from events which contain at least one fake lepton are estimated from data using the matrix.
Table 6: Event yields in the fake-lepton control region for all significant sources of background. The first uncertainty is the statistical one associated with the number of events in the samples, the second uncertainty is systematic and is described in Section 7. The entry labelled “other backgrounds” includes all the remaining backgrounds described in Section 3 and in Table 2. The signal efficiency is also shown.

method [75]. This is based on the measurement of the efficiencies of real and fake loose leptons to pass the nominal selection, $\epsilon_R$ and $\epsilon_F$, and on the selection of two orthogonal sets of events in the signal region. For the first of these sets, the nominal requirements are used for the leptonic selection, while for the second one, only the leptons which satisfy the looser selection (as described in Section 4) but without meeting the nominal requirements are considered. For the single-lepton case, the number of events with one fake nominal lepton is

$$N_{F}^{\text{nominal}} = (\epsilon_{F}/\epsilon_{R} - \epsilon_{F})((\epsilon_{R} - 1)N_{T} + \epsilon_{R}N_{L}),$$

where $N_{T}$ ($N_{L}$) represents the number of selected events in the first (second) set defined above. The method is extrapolated to the three-lepton topology, with a $8 \times 8$ matrix that is inverted using a numerical method to obtain the number of events with at least one fake lepton. The efficiencies for real and fake leptons are estimated as a function of the lepton transverse momentum by a fit of the matrix method results to two dedicated enriched samples of real and fake leptons: a sample of $Z \rightarrow \ell^{+}\ell^{-}, \ell = e, \mu$ and a same-sign dilepton sample (excluding same-flavour events with a reconstructed mass compatible with a $Z$ boson). In both samples, in order to improve the modelling of fake leptons originating from heavy-flavour decays, only events with at least one additional $b$-tagged jet are considered. The efficiency $\epsilon_R$ ranges from 0.74 to 0.88 (0.80 to 0.99) and $\epsilon_F$ from 0.010 to 0.13 (0.035 to 0.18) for electrons (muons). The relevant uncertainties are calculated from the discrepancy between predicted and observed number of events in the control region detailed below.

A control region to test the performance of the fake-lepton estimation method and derive its uncertainty is defined. It requires three leptons with $p_T < 50$ GeV (the third one with $p_T < 30$ GeV), two of them having the same flavour, opposite charge and a reconstructed mass within 15 GeV of the $Z$ boson mass, at least one $b$-tagged jet with $p_T > 35$ GeV and $E_T^{\text{miss}} < 40$ GeV. As for the $t\bar{t}Z$ control region, there is a small overlap with the signal region, which is not removed in order to increase the sensitivity to the fake-lepton backgrounds. The yields are shown in Table 6 and agree well between data and expectation. As a validation of the matrix method, the background in which exactly one of the leptons is a fake lepton is also evaluated using simulated samples. The results for the signal region and different control regions are consistent between the two methods within the estimated uncertainties.

Figure 2 shows the $p_T$ of the leading lepton for the ZZ, WZ and $t\bar{t}Z$ control regions, and the reconstructed mass of the two leptons with the same flavour and opposite charge for the fake-lepton control region.
Figure 2: Expected (filled histogram) and observed (points with error bars) distributions for the $p_T$ of the leading lepton in the (a) ZZ, (b) WZ and (c) $t\bar{t}Z$ control regions and (d) reconstructed mass of the two leptons with the same flavour and opposite charge in the fake-lepton control region. For comparison, distributions for the FCNC $t\bar{t} \rightarrow bWqZ$ signal (dashed line), scaled to $10^4$ or 10 times the observed 95% CL limit, are also shown. Background statistical uncertainties associated with the number of events in the samples are represented by the hatched areas.
7 Systematic uncertainties

The effect of each source of systematic uncertainty is studied by independently varying the corresponding central value and propagating this through the full analysis chain. The relative impact of each type of systematic uncertainty on the total background and signal is summarised in Table 7.

The main uncertainty on the backgrounds comes from their modelling, which has the following two contributions. The level of agreement with data of the reference samples is assessed from the combination of the Poisson uncertainty on the available amount of data with the statistical uncertainty of the expected background yields in the dedicated control regions described in Section 6. The uncertainties are estimated to be 6.3%, 12%, 42% and 62%, for the WZ, ZZ, t¯tZ and fake-lepton backgrounds, respectively. The other contribution comes from the uncertainty on the theoretical prediction in the signal region and is estimated using the alternative WZ and ZZ simulated samples. The corresponding uncertainties are 17% and 100%, respectively. Similarly, for t¯tZ, tZ and Higgs samples, conservative values of 30% [76, 77], 50% [74] and 15% [78] respectively, are used, in order to account for the theoretical uncertainties. The combination of all these uncertainties gives a 17% effect on the total background estimation.

The theoretical uncertainties of the signal modelling, as described in Section 3, namely production cross section and ISR/FSR modelling, are found to be 5.5%.

For both the estimated signal and background event yields, experimental uncertainties resulting from detector effects are considered. The lepton reconstruction, identification and trigger efficiencies, as well as lepton momentum scales and resolutions [63, 79, 80] are considered. The overall effect on the total background yield and the signal efficiency is estimated to be 4.7% and 2.9% respectively. The effect of the jet energy scale and resolution [66, 81] uncertainties are evaluated as 7.7% and 4.9% for the background and signal, respectively. The b-tagging performance component, which includes the uncertainty of the b-, c-, mistagged- and τ-jet scale factors (the τ and charm uncertainties are highly correlated and evaluated as such) is evaluated by varying the η-, pT- and flavour-dependent scale factors applied to each jet in the simulated samples. It is estimated to be 3.9% for the total background and 7.2% for the signal efficiency. The Emiss\text{\textsuperscript{T}} scale uncertainty [70] is found to vary the total background yield and the signal efficiency by 3.2% and 1.5%, respectively. All these detector systematic uncertainties are treated as fully correlated between signal and background.

The uncertainty related to the integrated luminosity for the dataset used in this analysis is 2.8%. It is derived following the methodology described in Ref. [82]. It only affects the estimations obtained from simulated samples, therefore its impact on the total background yield estimation is 2.4%.

8 Results

Table 8 shows the expected number of background events, number of selected data events and signal efficiency after the final event selection described in Section 5. Figure 3 shows the reconstructed masses of the top quarks and Z boson after the final selection. Good agreement between data and background yields is observed at all stages of the analysis. No evidence for the t → qZ decay is found and a 95% CL upper limit on the number of signal events is derived using the modified frequentist likelihood method [83, 84].
Table 7: Summary of the impact of each type of uncertainty on the total background and signal yields. The values are shown as the relative variations from the nominal values. The statistical uncertainty associated with the number of events in the simulated samples is also shown.

The test-statistic $X_d$, which compares the number of observed data events with background and signal expectations, is defined as:

$$X_d = n \ln \left(1 + \frac{s}{b}\right)$$  \hspace{1cm} (3)

where $n$, $s$ and $b$ are the numbers of data, expected background and signal events, respectively. The $X_d$ statistical test is then compared to $10^5$ pseudo-experiments for the hypotheses of signal plus background ($X_{s+b}$) and background-only ($X_b$), which are obtained by replacing $n$ with the corresponding number of events produced by each pseudo-experiment. The statistical fluctuations of the pseudo-experiments are implemented assuming that the number of events follows a Poisson distribution. All statistical and systematic uncertainties on the expected backgrounds and signal efficiencies, as described in Section 7, are taken into account and implemented assuming Gaussian distributions.
Figure 3: Expected (filled histogram) and observed (points with error bars) distributions in the signal region after the final selection is applied for the reconstructed masses of the (a) top quark from the FCNC decay, (b) top quark from the SM decay and (c) $Z$ boson. For comparison, distributions for the FCNC $t\bar{t} \rightarrow bWqZ$ signal (dashed line), normalised to the observed 95% CL limit, are also shown. Background statistical uncertainties are represented by the hatched areas.

The CL for a given signal hypothesis $s$ is defined as [83]:

$$1 - CL = \frac{\int_{X_d}^{X_d} P_{s+b}(X) dX}{\int_{X_b}^{X_b} P_b(X) dX},$$

(4)

where $P_{s+b}$ and $P_b$ are the probability density functions obtained from the pseudo-experiments for the $X_{s+b}$ and $X_b$ values, respectively, and are functions of $s$ and $b$. The limit on the number of signal events is determined by finding the value of $s$ corresponding to a CL of 95%. The expected limit is computed by replacing $X_d$ with the median of the statistical test for the background hypothesis ($X_b$).

The limits on the number of signal events are converted into upper limits on the $t \rightarrow qZ$ branching fraction using the NNLO+NNLL calculation, and uncertainty, for the $t\bar{t}$ cross section, and constraining $\text{BR}(t \rightarrow bW) = 1 - \text{BR}(t \rightarrow qZ)$. Table 9 shows the observed limit on $\text{BR}(t \rightarrow bW)$ together with the expected limit and corresponding $\pm 1\sigma$ bounds. These values are calculated using the reference $t\bar{t} \rightarrow bWcZ$ sample, since it gives a more conservative result than the $t\bar{t} \rightarrow bWuZ$ sample. The smaller $b$-tagged jet multiplicity of the $t\bar{t} \rightarrow bWuZ$ signal sample leads to an improvement of 4% in the limit.

Figure 4 compares the 95% CL observed limit found in this analysis with the results from other FCNC searches performed by the H1, ZEUS, LEP (combined results of the ALEPH, DELPHI, L3 and OPAL collaborations), CDF, DØ and CMS collaborations. The results presented in this paper are consistent with the ones from the CMS Collaboration.
Table 9: Observed and expected 95% CL limits on the FCNC top-quark decay BRs. The expected central value is shown together with the ±1σ bands, which includes the contribution from the statistical and systematic uncertainties.

Figure 4: The current 95% CL observed limits on the (a) BR(t → qγ) vs BR(t → qZ) and (b) BR(t → qH) vs BR(t → qZ) planes are shown. The full lines represent the results from the ATLAS [25], CDF [16, 21] CMS [19, 27], DØ [17], H1 [20], LEP (combined results of the ALEPH, DELPHI, L3 and OPAL collaborations) [10-14] and ZEUS [15] collaborations. The ATLAS lines correspond to the limit on BR(t → qZ) set in this paper.
9 Conclusions

A search for the FCNC top-quark decay $t \rightarrow qZ$ in events with three leptons has been performed using LHC data collected by the ATLAS experiment at a centre-of-mass energy of $\sqrt{s} = 8$ TeV and corresponding to an integrated luminosity of 20.3 fb$^{-1}$ recorded in 2012. No evidence for signal events is found and a 95% CL limit for the $t \rightarrow qZ$ branching fraction is established at $\text{BR}(t \rightarrow qZ) < 7 \times 10^{-4}$, in agreement with the expected limit of $\text{BR}(t \rightarrow qZ) < 8 \times 10^{-4}$.

Acknowledgements

We thank CERN for the very successful operation of the LHC, as well as the support staff from our institutions without whom ATLAS could not be operated efficiently.

We acknowledge the support of ANPCyT, Argentina; YerPhI, Armenia; ARC, Australia; BMWF and FWF, Austria; ANAS, Azerbaijan; SSTC, Belarus; CNPq and FAPESP, Brazil; NSERC, NRC and CFI, Canada; CERN; CONICYT, Chile; CAS, MOST and NSFC, China; COLCIENCIAS, Colombia; MSMT CR, MPO CR and VSC CR, Czech Republic; DNRF, DNSRC and Lundbeck Foundation, Denmark; IN2P3-CNRS, CEA-DSM/IRFU, France; GNSF, Georgia; BMBF, HGF, and MPG, Germany; GSRT, Greece; RGC, Hong Kong SAR, China; ISF, I-CORE and Benoziyo Center, Israel; INFN, Italy; MEXT and JSPS, Japan; CNRST, Morocco; FOM and NWO, Netherlands; RCN, Norway; MNiSW and NCN, Poland; FCT, Portugal; MNE/IFA, Romania; MES of Russia and NRC KI, Russian Federation; JINR; MESTD, Serbia; MSSR, Slovakia; ARRS and MIZŠ, Slovenia; DST/NRF, South Africa; MINECO, Spain; SRC and Wallenberg Foundation, Sweden; SERI, SNSF and Cantons of Bern and Geneva, Switzerland; MOST, Taiwan; TAEK, Turkey; STFC, United Kingdom; DOE and NSF, United States of America. In addition, individual groups and members have received support from BCKDF, the Canada Council, CANARIE, CRC, Compute Canada, QFRNT, and the Ontario Innovation Trust, Canada; EPLANET, ERC, FP7, Horizon 2020 and Marie Sklodowska-Curie Actions, European Union; Investissements d’Avenir Labex and Idex, ANR, Region Auvergne and Fondation Partager le Savoir, France; DFG and AvH Foundation, Germany; Herakleitos, Thales and Aristeia programmes co-financed by EU-ESF and the Greek NSRF; BSF, GIF and Minerva, Israel; BRF, Norway; the Royal Society and Leverhulme Trust, United Kingdom.

The crucial computing support from all WLCG partners is acknowledged gratefully, in particular from CERN and the ATLAS Tier-1 facilities at TRIUMF (Canada), NDGF (Denmark, Norway, Sweden), CC-IN2P3 (France), KIT/GridKA (Germany), INFN-CNAF (Italy), NL-T1 (Netherlands), PIC (Spain), ASGC (Taiwan), RAL (UK) and BNL (USA) and in the Tier-2 facilities worldwide.

143 SLAC National Accelerator Laboratory, Stanford CA, United States of America
144 (a) Faculty of Mathematics, Physics & Informatics, Comenius University, Bratislava; (b) Department of Subnuclear Physics, Institute of Experimental Physics of the Slovak Academy of Sciences, Kosice, Slovak Republic
145 (a) Department of Physics, University of Cape Town, Cape Town; (b) Department of Physics, University of Johannesburg, Johannesburg; (c) School of Physics, University of the Witwatersrand, Johannesburg, South Africa
146 (a) Department of Physics, Stockholm University; (b) The Oskar Klein Centre, Stockholm, Sweden
147 Physics Department, Royal Institute of Technology, Stockholm, Sweden
148 Departments of Physics & Astronomy and Chemistry, Stony Brook University, Stony Brook NY, United States of America
149 Department of Physics and Astronomy, University of Sussex, Brighton, United Kingdom
150 School of Physics, University of Sydney, Sydney, Australia
151 Institute of Physics, Academia Sinica, Taipei, Taiwan
152 Department of Physics, Technion: Israel Institute of Technology, Haifa, Israel
153 Raymond and Beverly Sackler School of Physics and Astronomy, Tel Aviv University, Tel Aviv, Israel
154 Department of Physics, Aristotle University of Thessaloniki, Thessaloniki, Greece
155 International Center for Elementary Particle Physics and Department of Physics, The University of Tokyo, Tokyo, Japan
156 Graduate School of Science and Technology, Tokyo Metropolitan University, Tokyo, Japan
157 Department of Physics, Tokyo Institute of Technology, Tokyo, Japan
158 Department of Physics, University of Toronto, Toronto ON, Canada
159 (a) TRIUMF, Vancouver BC; (b) Department of Physics and Astronomy, York University, Toronto ON, Canada
160 Faculty of Pure and Applied Sciences, University of Tsukuba, Tsukuba, Japan
161 Department of Physics and Astronomy, Tufts University, Medford MA, United States of America
162 Centro de Investigaciones, Universidad Antonio Narino, Bogota, Colombia
163 Department of Physics and Astronomy, University of California Irvine, Irvine CA, United States of America
164 (a) INFN Gruppo Collegato di Udine, Sezione di Trieste, Udine; (b) ICTP, Trieste; (c) Dipartimento di Chimica, Fisica e Ambiente, Università di Udine, Udine, Italy
165 Department of Physics, University of Illinois, Urbana IL, United States of America
166 Department of Physics and Astronomy, University of Uppsala, Uppsala, Sweden
167 Instituto de Física Corpuscular (IFIC) and Departamento de Física Atómica, Molecular y Nuclear and Departamento de Ingeniería Electrónica and Instituto de Microelectrónica de Barcelona (IMB-CNM), University of Valencia and CSIC, Valencia, Spain
168 Department of Physics, University of British Columbia, Vancouver BC, Canada
169 Department of Physics and Astronomy, University of Victoria, Victoria BC, Canada
170 Department of Physics, University of Warwick, Coventry, United Kingdom
171 Waseda University, Tokyo, Japan
172 Department of Particle Physics, The Weizmann Institute of Science, Rehovot, Israel
173 Department of Physics, University of Wisconsin, Madison WI, United States of America
174 Fakultät für Physik und Astronomie, Julius-Maximilians-Universität, Würzburg, Germany
175 Fachbereich C Physik, Bergische Universität Wuppertal, Wuppertal, Germany
176 Department of Physics, Yale University, New Haven CT, United States of America
177 Yerevan Physics Institute, Yerevan, Armenia
178 Centre de Calcul de l’Institut National de Physique Nucléaire et de Physique des Particules (IN2P3),
Villeurbanne, France

a Also at Department of Physics, King’s College London, London, United Kingdom
b Also at Institute of Physics, Azerbaijan Academy of Sciences, Baku, Azerbaijan
c Also at Novosibirsk State University, Novosibirsk, Russia
d Also at TRIUMF, Vancouver BC, Canada
e Also at Department of Physics, California State University, Fresno CA, United States of America
f Also at Department of Physics, University of Fribourg, Fribourg, Switzerland
g Also at Departamento de Fisica e Astronomia, Faculdade de Ciencias, Universidade do Porto, Portugal
h Also at Tomsk State University, Tomsk, Russia
i Also at CPPM, Aix-Marseille Université and CNRS/IN2P3, Marseille, France
j Also at Universita di Napoli Parthenope, Napoli, Italy
k Also at Institute of Particle Physics (IPP), Canada
l Also at Particle Physics Department, Rutherford Appleton Laboratory, Didcot, United Kingdom
m Also at Department of Physics, St. Petersburg State Polytechnical University, St. Petersburg, Russia
n Also at Louisiana Tech University, Ruston LA, United States of America
o Also at Institucio Catalana de Recerca i Estudis Avancats, ICREA, Barcelona, Spain
p Also at Graduate School of Science, Osaka University, Osaka, Japan
q Also at Department of Physics, National Tsing Hua University, Taiwan
r Also at Department of Physics, The University of Texas at Austin, Austin TX, United States of America
s Also at Institute of Theoretical Physics, Ilia State University, Tbilisi, Georgia
t Also at CERN, Geneva, Switzerland
u Also at Georgian Technical University (GTU), Tbilisi, Georgia
v Also at Manhattan College, New York NY, United States of America
w Also at Hellenic Open University, Patras, Greece
x Also at Institute of Physics, Academia Sinica, Taipei, Taiwan
y Also at LAL, Université Paris-Sud and CNRS/IN2P3, Orsay, France
z Also at Academia Sinica Grid Computing, Institute of Physics, Academia Sinica, Taipei, Taiwan
aa Also at School of Physics, Shandong University, Shandong, China
ab Also at Moscow Institute of Physics and Technology State University, Dolgoprudny, Russia
ac Also at Section de Physique, Université de Genève, Geneva, Switzerland
ad Also at International School for Advanced Studies (SISSA), Trieste, Italy
ae Also at Department of Physics and Astronomy, University of South Carolina, Columbia SC, United States of America
af Also at School of Physics and Engineering, Sun Yat-sen University, Guangzhou, China
ag Also at Faculty of Physics, M.V.Lomonosov Moscow State University, Moscow, Russia
ah Also at National Research Nuclear University MEPhI, Moscow, Russia
ai Also at Department of Physics, Stanford University, Stanford CA, United States of America
aj Also at Institute for Particle and Nuclear Physics, Wigner Research Centre for Physics, Budapest, Hungary
ak Also at University of Malaya, Department of Physics, Kuala Lumpur, Malaysia
