Received 23 April 2014

In concurrency theory, various semantic equivalences on transition systems are based on traces decorated with some additional observations, generally referred to as decorated traces. Using the generalized powerset construction, recently introduced by a subset of the authors (Silva, Bonchi, Bonsangue & Rutten 2010), we give a coalgebraic presentation of decorated trace semantics. The latter include ready, failure, (complete) trace, possible-futures, ready trace and failure trace semantics for labeled transition systems, and ready, (maximal) failure and (maximal) trace semantics for generative probabilistic systems. This yields a uniform notion of minimal representatives for the various decorated trace equivalences, in terms of final Moore automata. As a consequence, proofs of decorated trace equivalence can be given by coinduction, using different types of (Moore-) bisimulation (up-to context).

1. Introduction

The study of behavioural equivalence of systems has been a research topic in concurrency for many years now. For different types of systems, several equivalences have been proposed throughout the years, each of which suitable for use in different contexts of application.

The focus of this paper is on labeled transition systems (LTS’s) and generative probabilistic systems (GPS’s) and a suite of corresponding equivalences usually referred to as decorated trace semantics. More explicitly, we consider ready, failure, (complete) trace, possible-futures, ready trace and failure trace semantics for LTS’s, as described in (van Glabbeek 2001) and ready, (maximal) failure and (maximal) trace semantics for GPS’s, as introduced in (Jou & Smolka 1990).

Proof methods for the different equivalences are an important part of this research enterprise. In this paper, we propose coinduction as a general proof method for the aforementioned decorated trace semantics of LTS’s and GPS’s.

Coinduction is a general proof principle which has been uniformly defined in the theory of coalgebras for different types of state-based systems and infinite data types. Given a
functor $\mathcal{F} : \text{Set} \to \text{Set}$, an $\mathcal{F}$-coalgebra is a pair $(X, f)$ consisting of a set of states $X$ and a function $f : X \to \mathcal{F}(X)$ defining the dynamics of the system. The functor $\mathcal{F}$ determines the type of the transition system or data type under study. For a large class of functors $\mathcal{F}$, there exists a final coalgebra into which every $\mathcal{F}$-coalgebra is mapped by a unique homomorphism. Intuitively, one can see the final coalgebra as the universe of all behaviours of systems and the unique morphism as the map assigning to each system its behaviour. This provides a standard notion of equivalence called $\mathcal{F}$-behavioural equivalence. Moreover, these canonical behaviours are minimal, by general coalgebraic considerations (Rutten 2000), in that no two different states are equivalent.

LTS’s can be modelled as coalgebras for the functor $\mathcal{L}(X) = (\wp(X))^A$ and the canonical behavioural equivalence associated with $\mathcal{L}$ is precisely the finest equivalence of the spectrum in (van Glabbeek 2001). Orthogonally, GPS’s are coalgebras for $\mathcal{G}(X) = \mathcal{D}_{\omega}(A \times X)$, where $\mathcal{D}_{\omega}$ is the (sub)probability functor. The behavioural equivalence associated to $\mathcal{G}$ is the probabilistic bisimilarity equivalence in (Jou & Smolka 1990).

In the recent past, other equivalences of the spectrum have been also cast in the coalgebraic framework. Notably, trace semantics of LTS’s was widely studied (Lenisa 1999, Lenisa, Power & Watanabe 2000, Hasuo, Jacobs & Sokolova 2007, Silva et al. 2010) and, more recently, decorated trace semantics was recovered in (Silva, Bonchi, Bonsangue & Rutten 2013) via a coalgebraic generalization of the classical powerset construction (Silva et al. 2010, Lenisa 1999, Cancila, Honsell & Lenisa 2003). This paved the way to a coalgebraic modelling of a series of “twin” semantics in the context of GPS’s, which we provide in this paper.

In the right hand side of Fig. 1 we illustrate the hierarchy (based on the coarseness level) among bisimilarity, ready, failure, (complete) trace, possible-futures, ready trace and failure trace semantics for LTS’s, as introduced in (van Glabbeek 2001). In the left hand side a similar hierarchy is depicted for bisimilarity, ready, (maximal) failure and (maximal) trace semantics for GPS’s, as in (Jou & Smolka 1990). For example, for both types of systems, bisimilarity (the standard behavioural equivalence on $\mathcal{F}$-coalgebras) is the finest of the semantics, whereas trace is the coarsest one. Moreover, note that for the case of GPS’s, maximality does not bring more distinguishing power and, ready and failure semantics are equivalent. In order to get some intuition on the type of distinctions the equivalences above encompass, consider the following LTS’s:

None of the top states of the systems above are bisimilar. The state $p$ is the only among the four in which an action $a$ can lead to a deadlock state, whereas $q, r$ and $s$ have a different branching structures.

The traces of the states $p, q, r$ and $s$ are $\{a, ab, ac\}$, and therefore they are all trace equivalent. Of the four states above, $q$ and $r$ and $s$ are complete trace equivalent as they can execute the same traces that lead to states where no further action are possible, whereas $p$ is the only state that can trigger $a$ and terminate.
A coalgebraic view on decorated traces

LTS’s:

\[
\begin{array}{c}
\text{bisimilarity} \\
\text{possible-futures} \\
\text{ready trace} \\
\text{failure trace} \\
\text{failure} \\
\text{complete trace} \\
\text{trace}
\end{array}
\]

GPS’s:

\[
\begin{array}{c}
\text{bisimilarity} \\
\text{ready} \\
\text{(max.) failure}
\end{array}
\]

Fig. 1. Lattices of semantic equivalences for LTS’s and GPS’s.

Ready (respectively, failure) semantics identifies states according to the set of actions they can (respectively, fail to) trigger immediately after a certain trace has been executed. None of the states above are ready equivalent; for example, after the execution of action \(a\), process \(p\) can reach a deadlock state whereas \(q\) has always to choose between actions \(b\) and \(c\). Orthogonally, only \(r\) and \(s\) are failure equivalent.

Possible-futures semantics identifies states that can perform the same traces \(w\) and, moreover, the states reached by executing such \(w\)’s are trace equivalent. None of the states above are possible-futures equivalent. For example, after triggering action \(a\), \(p\) can reach a deadlock state (with no further behaviour) whereas \(q\) can execute the set of traces \(\{b,c\}\).

Ready (respectively failure) trace semantics identifies states that can trigger the same traces \(w\) and the (pairwise-taken) intermediate states determined by such \(w\)’s are ready (respectively refuse) to trigger the same sets of actions. None of the systems above is ready trace equivalent. For example, after performing action \(a\), process \(q\) reaches a state that is ready to trigger both \(b\) and \(c\), whereas \(r\) cannot. The analysis on failure trace equivalence follows a similar reasoning, but different results.

The corresponding semantic equivalences in Fig. 1 distinguish between \(p, q, r\) and \(s\) as summarized in the table below:

where ✓ to stands for an “yes” answer w.r.t. the behavioural equivalence of two of the states p, q, r and s, whereas × represents a “no” answer.

Intuitively, generative probabilistic systems (GPS’s) resemble LTS’s, with the difference that each transition is labelled by both an action and the probability of that action being executed. For more insight on decorated trace semantics for GPS’s, consider the following systems:

In the setting of GPS’s, decorated trace semantics take into consideration paths w which can be executed by a probabilistic process p. Reasoning on the corresponding equivalences is based on the sum of probabilities of occurrence of such w’s that, for example, lead p to a set of processes, for the case of trace semantics, or to a set of processes that (fail to) trigger the same sets of actions as a first step, for ready (respectively, failure) semantics.

In (Jou & Smolka 1990) a notion of maximality was introduced for the case of trace and failure semantics. Intuitively, the former takes into consideration the probability of a process p to execute a certain trace w and terminate, whereas the latter takes into consideration the largest set of actions p fails to trigger as a first step after the execution of w. However, it has been proven in (Jou & Smolka 1990) that maximality does not increase the distinguishing power of decorated trace semantics and, moreover, ready and failure equivalence of GPS’s coincide.

With respect to (maximal) trace semantics, amongst the systems above, p’ and q’ are equivalent: they have the same probability of executing traces w ∈ {ε, a, ab, abc, abd}. Moreover, each such w leads p’ and q’ to sets of processes S1, S2 ready to fire the same actions. Consequently, S1 and S2 fail to trigger the same sets of actions as a first step. Hence, p’ and q’ are ready and (maximal) failure equivalent as well. None of the processes above are bisimilar: the corresponding states reached via transitions labelled a (with total probability 1) display different behaviour as they either have different branching structure, or can trigger different actions.

This paper is an extended version of the conference paper (Bonchi, Bonsangue, Caltais, Rutten & Silva 2012) where we (a) proved that the coalgebraic ready, failure and (complete) trace semantics for LTS’s are equivalent to the corresponding set-theoretic notions from (van Glabbeek 2001), (b) showed how the coalgebraic semantics lead to canonical representatives for the aforementioned decorated traces, and (c) showed how to prove decorated trace equivalence of LTS’s using coinduction, by constructing bisimulations (up-to context) that witness the desired equivalence. The latter is interesting also from the point of view of tool development: construction of bisimulations is known to be particularly suitable for automation. Moreover, the up-to context technique also increases the efficiency of reasoning, as verifications are performed under certain closure properties, which means that the bisimulations which are built are smaller (see Section 7 for an example). The techniques we used for up-to context reasoning on LTS’s are an extension of the recent work in (Bonchi & Pous 2013).
In this paper we extend (a), (b) and (c) above also for the case of possible-futures, ready trace and failure trace semantics for LTS’s and for several equivalences on GPS’s. We provide (more) details, proofs and examples on how to use the coalgebraic framework (summarized in Fig. 10) for reasoning on decorated trace equivalences for both the case of LTS’s and GPS’s. We also show that the spectrum of decorated trace semantics in Fig. 1 can be recovered from the coalgebraic modelling.

The paper is organized as follows. In Section 2, we provide the basic notions from coalgebra and recall the generalized powerset construction. In Section 3 and Section 4, we show how the powerset construction can be applied for determinizing LTS’s and GPS’s, respectively, in terms of Moore automata \((X, f: X \rightarrow B \times X^A)\), in order to coalgebraically characterize the corresponding decorated trace semantics. Here we also prove that the obtained coalgebraic models are equivalent to the original definitions, and illustrate how one can reason about decorated trace equivalence by constructing (Moore) bisimulations. A compact overview on the uniform coalgebraic framework is given in Section 5. Section 6 discusses that the canonical representatives of LTS’s and GPS’s we obtain coalgebraically coincide with the corresponding minimal automata one would obtain by identifying all states equivalent w.r.t. a particular decorated trace semantics. In Section 7 we introduce bisimulations up-to context and emphasize on their efficiency by means of an example for LTS’s. Finally, Section 8 contains concluding remarks and discusses future work.

2. Preliminaries

In this section, we briefly recall basic notions from coalgebra and the generalized powerset construction (Silva et al. 2010, Lenisa 1999, Cancila et al. 2003). We first introduce some notation on sets.

We denote sets by capital letters \(X, Y, \ldots\) and functions by lower case letters \(f, g, \ldots\). The cartesian product of two sets \(X\) and \(Y\) is denoted by \(X \times Y\), and has the projection maps \(\pi_1: X \times Y \rightarrow X\) and \(\pi_2: X \times Y \rightarrow Y\). By \(X^Y\) we represent the family of functions \(f: Y \rightarrow X\), whereas the collection of finite subsets of \(X\) is denoted by \(P_{\omega}X\). The collection of all subsets of \(X\) is denoted by \(P(X)\). For each of these operations defined on sets, there is an analogous one on functions (for details see for example (Awodey 2010)). This turns the operations above into (bi)functors, which we shall use throughout this paper.

For an alphabet \(A\), we denote by \(A^*\) the set of all words over \(A\) and by \(\varepsilon\) the empty word. The concatenation of words \(w_1, w_2 \in A^*\) is written \(w_1w_2\).
2.1. Coalgebra and bisimulation

We consider coalgebras of set functors $\mathcal{F} : \text{Set} \to \text{Set}$. An $\mathcal{F}$-coalgebra (or coalgebra, when $\mathcal{F}$ is understood) is a pair $(X, c : X \to \mathcal{F}X)$. We call $X$ the state space, and we say that $\mathcal{F}$ together with $c$ determine the dynamics, or the transition structure of the $\mathcal{F}$-coalgebra.

An $\mathcal{F}$-homomorphism between two $\mathcal{F}$-coalgebras $(X, f)$ and $(Y, g)$, is a function $h : X \to Y$ preserving the transition structure, i.e., $g \circ h = \mathcal{F}(h) \circ f$. $\mathcal{F}$-coalgebras and $\mathcal{F}$-homomorphisms form a category denoted by $\text{Coalg}(\mathcal{F})$.

An $\mathcal{F}$-coalgebra $(\Omega, \omega)$ is final if for any $\mathcal{F}$-coalgebra $(X, f)$ there exists a unique $\mathcal{F}$-homomorphism $\llbracket - \rrbracket_X : X \to \Omega$. A final coalgebra represents the universe of all possible behaviours of $\mathcal{F}$-coalgebras. The unique morphism $\llbracket - \rrbracket_X : X \to \Omega$ maps each state in $X$ to its behaviour. Using this mapping, behavioural equivalence can be defined as follows: for any two coalgebras $(X, f)$ and $(Y, g)$, the states $x \in X$ and $y \in Y$ are behaviourally equivalent, written $x \sim_\mathcal{F} y$, if and only if they have the same behaviour, that is

$$x \sim_\mathcal{F} y \text{ iff } \llbracket x \rrbracket_X = \llbracket y \rrbracket_Y. \quad (1)$$

We think of $\llbracket - \rrbracket_X$ as the canonical representative of the behaviour of $x$. The image of $X$ under $\llbracket - \rrbracket_X$ can be viewed as the minimization of $(X, f)$, since the final coalgebra contains no pairs of equivalent states.

For an example we consider deterministic automata (DA’s). A deterministic automaton over the input alphabet $A$ is a pair $(X, (o, t))$, where $X$ is a set of states and $(o, t) : X \to 2 \times X^A$ is a function with two components: $o$, the output function, determines if a state $x$ is final ($o(x) = 1$) or not ($o(x) = 0$); and $t$, the transition function, returns for each input letter $a$ the next state. DA’s are coalgebras for the functor $\mathcal{D}(X) = 2 \times X^A$. The final coalgebra of this functor is $(2^{A^*}, (\varepsilon, (\cdot)_a))$ where $2^{A^*}$ is the set of languages over $A$ and $(\varepsilon, (\cdot)_a)$, given a language $L$, determines whether or not the empty word $\varepsilon$ is in the language ($\varepsilon(L) = 1$ or $\varepsilon(L) = 0$ resp.) and, for each input letter $a$, returns the derivative of $L$: $L_a = \{w \in A^* \mid aw \in L\}$. From any DA, there is a unique map $\llbracket - \rrbracket$ into $2^{A^*}$ which assigns to each state its behaviour (that is, the language that the state recognizes).

$$\begin{array}{c}
X \xrightarrow{(o, t)} 2 \times X^A \xrightarrow{id \times [\llbracket - \rrbracket_\mathcal{D}]} 2 \times (2^{A^*})^A \\
\llbracket x \rrbracket_X(\varepsilon) = o(x) \\
\llbracket x \rrbracket_X(aw) = \llbracket t(x)(a) \rrbracket_X(w)
\end{array}$$

Therefore, behavioural equivalence for the functor $\mathcal{D}$ coincides with the classical language equivalence of automata.

Another example (fundamental for the rest of the paper) is given by Moore automata. Moore automata with inputs in $A$ and outputs in $B$ are coalgebras for the functor $\mathcal{M}(X) = B \times X^A$, that is pairs $(X, (o, t))$ where $X$ is a set, $t : X \to X^A$ is the transition function (like for DA) and $o : X \to B$ is the output function which maps every state in its output. Thus DA can be seen as a special case of Moore automata where $B = 2$. The final coalgebra for $\mathcal{M}$ is $(B^{A^*}, (\varepsilon, (\cdot)_a))$ where $B^{A^*}$ is the set of all functions $\varphi : A^* \to B$, $\varepsilon : B^{A^*} \to B$ maps each $\varphi$ into $\varphi(\varepsilon)$ and $(\cdot)_a : B^{A^*} \to (B^{A^*})^A$ is defined
A coalgebraic view on decorated traces

7

for all \( \varphi \in B^A \), \( a \in A \) and \( w \in A^* \) as \( (\varphi)_{a}(w) = \varphi(aw) \).

\[
\begin{array}{c}
X \xrightarrow{(o,t)} B^A^* \\
\downarrow \downarrow \\
B \times X^A \xrightarrow{id \times [-,-]} B \times (B^A)^A \\
\end{array}
\]

\[
\begin{array}{c}
\llbracket x \rrbracket (\varepsilon) = o(x) \\
\llbracket x \rrbracket (aw) = \llbracket t(x)(a) \rrbracket X(w)
\end{array}
\]

Coalgebras provide a useful technique for proving behavioural equivalence, namely, bisimulation. Let \((X,f)\) and \((Y,g)\) be two \( F \)-coalgebras. A relation \( R \subseteq X \times Y \) is a bisimulation if there exists a function \( \alpha_R: R \rightarrow F \) such that \( \pi_1: R \rightarrow X \) and \( \pi_2: R \rightarrow Y \) are coalgebra homomorphisms. In (Rutten 2000), it is shown that under certain conditions on \( F \) (which are met by all the functors considered in this paper), bisimulations are a sound and complete proof technique for behavioural equivalence, namely,

\[
x \sim_F y \iff \text{there exists a bisimulation } R \text{ such that } xRy.
\] (2)

2.2. The generalized powerset construction

As shown above, every functor \( F \) induces both a notion of \( F \)-coalgebra and a notion of behavioural equivalence \( \sim_F \). Sometimes, it is interesting to consider different equivalences than \( \sim_F \) for reasoning about \( F \)-coalgebras. This is the case of LTS’s and GPS’s which can be modelled as coalgebras for the functor \( \mathcal{L}(X) = (P_\omega X)^A \) and \( \mathcal{G}(X) = D_\omega(A \times X) \), respectively. The corresponding induced behavioural equivalences \( \sim_\mathcal{L} \) and \( \sim_\mathcal{G} \) coincide with the standard notion of bisimilarity (Park 1981, Milner 1989) and probabilistic bisimilarity (Jou & Smolka 1990), respectively. However, in concurrency theory, many other equivalences have been studied, notably, decorated trace equivalences (van Glabbeek 2001, Jou & Smolka 1990). Another example is given by non-deterministic automata (NDA’s) which are coalgebras for the functor \( \mathcal{N}(X) = 2 \times (P_\omega X)^A \). The associated equivalence \( \sim_\mathcal{N} \) strictly implies language equivalence, which is often the intended semantics.

With this intuition in mind, we refer to the generalized powerset construction (Silva et al. 2010, Lenisa 1999, Cancila et al. 2003) for coalgebras \( f: X \rightarrow JT(X) \) for a functor \( F \) and a monad \((T,\eta,\mu)\), with the proviso that that \( JT(X) \) is an algebra for \( T \). Recall that a \( T \)-algebra for a monad \((T,X,\mu,\eta)\) is a pair \((X,h: T(X) \rightarrow X)\) satisfying the laws \( h \circ \eta = id \) and \( h \circ \mu = h \circ Th \). For the case \( T = P_\omega \), \( T \)-algebras are semilattices (with bottom).

We briefly summarize the aforementioned construction, for the case when \( F \) has a final coalgebra \((\Omega,\omega)\), as in the following commuting diagram:

\[
\begin{array}{c}
X \xrightarrow{\eta} T(X) \xrightarrow{[-,-]} \Omega \\
\downarrow f \downarrow \downarrow f^\circ \\
JT(X) \xrightarrow{\llbracket [-,-] \rrbracket} \Omega
\end{array}
\]

(3)

(We refer the interested reader to (Silva et al. 2013) where all the technical details are explored and many instances of the construction are shown.)
Intuitively, the coalgebra \( f : X \to \mathcal{F}T(X) \) is extended to \( f^\sharp : T(X) \to \mathcal{F}T(X) \) which, for two elements \( x_1, x_2 \in X \), enables checking their "\( \mathcal{F} \)-equivalence with respect to the monad \( T \) (\( \eta(x_1) \sim_\mathcal{F} \eta(x_2) \)) rather than checking their \( \mathcal{F}T \)-equivalence.

Formally, \( f^\sharp \) is the unique algebra map between \( (T(X), \mu) \) and \( (\mathcal{F}T X, h) \) (where \( h \) is a given algebra structure on \( \mathcal{F}T X \)) such that \( f^\sharp \circ \eta = f \). Moreover, one can show that, under certain additional conditions, also \( \Omega \) has an algebra structure and that \( [-] \) is also an algebra map (Silva et al. 2013).

**Remark 2.1.** Based on (1) and (2), verifying \( \mathcal{F} \)-behavioural equivalence of two states \( x_1, x_2 \) in a coalgebra \( (T(X), f^\sharp) \) consists in identifying a bisimulation \( R \) relating \( \eta(x_1) \) and \( \eta(x_2) \):

\[
\llbracket \eta(x_1) \rrbracket = \llbracket \eta(x_2) \rrbracket \text{ iff } \eta(x_1) R \eta(x_2).
\] (4)

Take, for example, the case of NDA’s which are \( \mathcal{F}T \)-coalgebras for \( \mathcal{F}(X) = 2 \times X^A \) and the monad \( T(X) = (\wp(\omega X), \eta, \mu) \), where

\[
\eta : X \to \wp(\omega X) \quad \mu : \wp(\wp(\omega X)) \to \wp(\omega X) \\
\eta(x) = \{x\} \quad \mu(U) = \bigcup_{S \subseteq U} S.
\]

Note that \( \mathcal{F}T(X) \) is a \( T \)-algebra, that is a semilattice, since \( 2 \cong \wp(1) \) is a semilattice and, moreover, product and exponentiation preserve the algebra structure. Therefore, according to the diagram above, every NDA \( (X, f) \) is transformed into \( (\wp(\omega X), f^\sharp) \) which is a DA. This corresponds to the classical powerset construction for determining non-deterministic automata. The language recognized by a state \( x \) can be defined by precomposing the unique morphism \( \llbracket - \rrbracket : \wp(\omega X) \to 2^A \) with the unit of \( \wp(\omega) \). Consequently, this enables reasoning on language equivalence of states of NDA’s, in terms of bisimulations.

In this paper we exploit the coalgebraic modelling of the powerset construction and derive a framework for handling decorated trace semantics of both LTS’s and GPS’s in terms of (final) Moore coalgebras, in a uniform fashion. We will only be interested in the case \( \mathcal{F}(X) = M(X) = B \times X^A \), for \( A \) an action alphabet and \( B \) a \( T \)-algebra. (Intuitively, \( B \) captures the decorations of interest for each of the semantics under consideration.)

To model GPS’s we consider the (sub)probability distribution monad \( (\mathcal{D}_\omega(X), \eta, \mu) \) where

\[
\eta : X \to \mathcal{D}_\omega(X) \\
\eta(x) = \lambda y. \begin{cases} 1 & \text{if } x = y \\ 0 & \text{otherwise} \end{cases} \\
\mu : \mathcal{D}_\omega(\mathcal{D}_\omega(X)) \to \mathcal{D}_\omega(X) \\
\mu(\psi) = \lambda x. \sum_{\varphi \in \text{supp}(\psi)} \varphi(x) \times \psi(\varphi)
\]

The algebras for this monad are the so-called positive convex structures (Doberkat 2008).

In (Silva et al. 2013), it is shown that the function mapping a \( \mathcal{F}T \)-coalgebra \( f \) to the \( \mathcal{F} \)-colagebra \( f^\sharp \) extends to a functor \( D : \text{Coalg}(\mathcal{F}T) \to \text{Coalg}(\mathcal{F}) \) assigning to each \( \mathcal{F}T \)-homomorphism \( h \) the \( \mathcal{F} \)-homomorphism \( T(h) \). For later use, we fix \( \text{Det}(\mathcal{F}T) \) to be the image of \( \text{Coalg}(\mathcal{F}T) \) through \( D \) and we prove the following lemma.

**Lemma 2.1.** Let \( (TX, f^\sharp) \) and \( (TY, g^\sharp) \) be coalgebras in \( \text{Det}(\mathcal{F}T) \) and let \( \approx_\mathcal{F} \) be the largest bisimulation on \( \text{Det}(\mathcal{F}T) \). Then, for all \( x \in TX \), \( y \in TY \), \( x \approx_\mathcal{F} y = x \sim_\mathcal{F} y \).
A coalgebraic view on decorated traces

Proof. Since $\text{Det}(\mathcal{F}T)$ is a subcategory of $\text{Coalg}(\mathcal{F})$, then every bisimulation in $\text{Det}(\mathcal{F}T)$ is also a bisimulation in $\text{Coalg}(\mathcal{F})$ and therefore $\approx_{\mathcal{F}} \subseteq \approx_{\mathcal{F}T}$.

For the other direction, take a bisimulation $R \subseteq TX \times TY$, $\pi_1: R \rightarrow TX$, $\pi_2: R \rightarrow TY$ and an $\mathcal{F}$-coalgebra structure $r: R \rightarrow \mathcal{F}R$. The latter $f^1$ and $g^1$ can be post-composed with $\mathcal{F}r$ and, in this way, both $\pi_1$ and $\pi_2$ are $\mathcal{F}T$-homomorphisms. As a consequence $(TTX, (\mathcal{F}(\eta) \circ f^1)^\sharp (TR, (\mathcal{F}(\eta) \circ r)^\sharp) \mathcal{F}(\pi_2) (TTX, (\mathcal{F}(\eta) \circ f^1)^\sharp)$ is a span in $\text{Det}(\mathcal{F}T)$. By routine calculation (???), one can show that $f^1 \circ \mu = (\mathcal{F}(\eta) \circ f^1)^\sharp$ and $g^1 \circ \mu = (\mathcal{F}(\eta) \circ g^1)^\sharp$ and thus $(TX, f^1) \mu \mathcal{F}(\pi_1) (TR, (\mathcal{F}(\eta) \circ r)^\sharp) \mathcal{F}(\pi_2) (TX, f^1)$ is a span in $\text{Coalg}(\mathcal{F})$.\]

3. Decorated trace semantics of LTS’s via determinization

In this section, our aim is to provide a coalgebraic view on decorated trace equivalences of LTS’s. We use the generalized powerset construction and show how one can determine arbitrary labelled transition systems obtaining particular instances of Moore automata (with different output sets) in order to model ready, failure, (complete) trace, possible-futures semantics of LTS’s. We use the generalized powerset construction and show how one can determinize an arbitrary semilattice with a $\lor$ operation, instantiated for each of the semantics under consideration as in (Silva et al. 2013). Then, the decorated LTS is determinized, as depicted in Figure 2.

Note that both the output operation and its image are parameterized by $I$, which will vary depending on the type of decorated trace semantics under consideration.

The coalgebraic modelling of possible-futures semantics could easily be recovered by following a similar approach. However, for the case of ready and failure trace semantics the transition structure of the LTS also needs to be slightly modified before the determinization. This consists in changing the alphabet $A$ to include additional information represented by sets of actions ready to be triggered as a first step. Consequently, each LTS $(X, \delta: X \rightarrow (\mathcal{P}_w X)^A)$ is uniquely associated a coalgebra $(X, (\overline{\sigma}_T, \delta: X \rightarrow (\mathcal{P}_w X)^A))$, with $I$.
defined in a natural fashion, as we shall see later on. The construction in Fig. 2 is then applied on \((X, (\overline{\delta}, \bar{\delta}))\).

The explicit instantiations of \(\overline{\sigma}\) and \(B_I\) are provided later in this section, where we will also show that the coalgebraic modelling in fact coincides with the original definitions of the corresponding equivalences. This was not formally shown in (Silva et al. 2013), for none of the aforementioned semantics.

Our coalgebraic modelling of decorated trace semantics enables the definition of the corresponding equivalences as Moore bisimulations (Rutten 2000) (i.e., bisimulations for a functor \(M = B_I \times X^A\)). This way, checking behavioural equivalence of \(x_1\) and \(x_2\) reduces to checking the equality of their unique representatives in the final coalgebra: \([[\{x_1\}]] = [[\{x_2\}]]\).

In the subsequent sections we a) provide the details on the coalgebraic modelling of ready, failure, (complete) trace, possible-futures, ready trace and failure trace semantics, b) show that the corresponding representations coincide with their original definitions in (van Glabbeek 2001) and c) show, by means of examples, how the associated coalgebraic framework can be used in order to reason on (some of) the aforementioned equivalences in terms of Moore bisimulations.

3.1. Ready and failure semantics

In this section we show how the ingredients of Fig. 2 can be instantiated in order to provide a coalgebraic modelling of ready and failure semantics. Moreover, we prove that the resulting coalgebraic characterizations of these semantics are equivalent to their original definitions in (van Glabbeek 2001).

Consider an LTS \((X, \delta: X \to (\mathcal{P}_\omega X)^A)\) and define, for a function \(\varphi: A \to \mathcal{P}_\omega X\), the set of actions enabled by \(\varphi\):

\[ I(\varphi) = \{ a \in A \mid \varphi(a) \neq \emptyset \}, \quad (5) \]

and the set of actions \(\varphi\) fails to enable:

\[ \text{Fail}(\varphi) = \{ Z \subseteq A \mid Z \cap I(\varphi) = \emptyset \}. \]

For the particular case \(\varphi = \delta(x)\), \(I(\delta(x))\) denotes the set of all (initial) actions ready to

![Fig. 2. The powerset construction for decorated LTS's.](image-url)
be fired by \( x \in X \), and \( \text{Fail}(\delta(x)) \) represents the set of subsets of all (initial) actions that cannot be triggered by such \( x \).

A \textit{ready pair} of \( x \) is a pair \((w, Z) \in A^* \times \mathcal{P}_\omega A\) such that \( x \xrightarrow{w} y \) and \( Z = I(\delta(y))\). A \textit{failure pair} of \( x \) is a pair \((w, Z) \in A^* \times \mathcal{P}_\omega A\) such that \( x \xrightarrow{w} y \) and \( Z \in \text{Fail}(\delta(y))\). We denote by \( R(x) \) and \( F(x) \), respectively, the sets of all \textit{ready pairs} and \textit{failure pairs}, respectively, associated to \( x \).

Intuitively, \textit{ready semantics} identifies states in \( X \) based on the actions \( a \in A \) they can immediately trigger after performing a certain action sequence \( w \in A^* \), \textit{i.e.}, based on their ready pairs. It was originally defined as follows:

\textbf{Definition 3.1} (\( R \)-\textit{equivalence} (van Glabbeek 2001)). Let \((X, \delta : X \rightarrow (\mathcal{P}_\omega X)^A)\) be an LTS and \( x, y \in X \) two states. States \( x \) and \( y \) are \textit{ready equivalent} (\( R \)-\textit{equivalent}) if and only if they have the same set of ready pairs, that is \( R(x) = R(y) \).

\textit{Failure semantics} identifies behaviours of states in \( X \) according to their failure pairs.

\textbf{Definition 3.2} (\( F \)-\textit{equivalence} (van Glabbeek 2001)). Let \((X, \delta : X \rightarrow (\mathcal{P}_\omega X)^A)\) be an LTS and \( x, y \in X \) two states. States \( x \) and \( y \) are \textit{failure equivalent} (\( F \)-\textit{equivalent}) if and only if \( F(x) = F(y) \), where

\[ F(x) = \{ (w, Z) \in A^* \times \mathcal{P}_\omega A \mid \exists x' \in X. x \xrightarrow{w} x' \wedge Z \in \text{Fail}(\delta(x')) \} .\]

The coalgebraic modelling of \textit{ready}, respectively, \textit{failure semantics} is obtained in a uniform fashion, by instantiating the ingredients of Fig. 2 as follows. For \( I \in \{ R, F \} \), \( \sigma_I : X \rightarrow \mathcal{P}_\omega (\mathcal{P}_\omega A) \) is defined as:

\[ \sigma_R(x) = \{ I(\delta(x)) \} \quad \sigma_F(x) = \text{Fail}(\delta(x)). \]

Intuitively, in the setting of \textit{ready semantics}, the observations provided by the output operation refer to the sets of actions ready to be executed by the states of the LTS. Similarly, for \textit{failure semantics}, the output operation refers to the sets of actions the states of the LTS cannot immediately fire.

\textbf{Remark 3.1.} Observe that the codomain of \( \bar{\delta}_R \) is \( \mathcal{P}_\omega (\mathcal{P}_\omega A) \), and not \( \mathcal{P}_\omega A \), as one might expect. However, this is consistent with the intended semantics. For \( B_I = B_R = B_F = \mathcal{P}_\omega (\mathcal{P}_\omega A) \), the final Moore coalgebra has carrier \( \mathcal{P}_\omega (\mathcal{P}_\omega A)^{A^*} \) which is isomorphic to \( \mathcal{P}(A^* \times \mathcal{P}_\omega (A)) \) the type of \( R(x) \) and \( F(x) \). The unique homomorphism into the final coalgebra will associate to each state \( \{ x \} \) a function that for each \( w \in A^* \) returns a set containing all sets \( R_{x'} \) of ready (resp. failed) actions triggered by all \( x' \) such that \( x \xrightarrow{w} x' \), for \( x, x' \in X \).

Next, we will prove the equivalence between the coalgebraic modelling of \textit{ready} and \textit{failure semantics} and their original definitions, presented above. More explicitly, given an arbitrary LTS \((X, \delta : X \rightarrow (\mathcal{P}_\omega X)^A)\) and a state \( x \in X \), we want to show that \( \{ \{ x \} \} \) is equal to \( I(x) \), for \( I \in \{ R, F \} \), depending on the semantics of interest.

The behaviour of a state \( x \in X \) is a function \( \{ \{ x \} \} : A^* \rightarrow \mathcal{P}_\omega (\mathcal{P}_\omega A) \), whereas \( I(x) \) is defined as a set of pairs in \( A^* \times \mathcal{P}_\omega A \). We represent the set \( I(x) \in \mathcal{P}(A^* \times \mathcal{P}_\omega A) \) by a
function $\varphi^\mathcal{R}_x: \mathcal{P}_\omega(\mathcal{P}_\omega A)^A$, where, for $w \in A^*$,

$$
\varphi^\mathcal{R}_x(w) = \{ Z \subseteq A \mid x \xrightarrow{w} y \land Z = I(\delta(y))\}
$$

$\varphi^\mathcal{T}_x(w) = \{ Z \subseteq A \mid x \xrightarrow{w} y \land Z \in \text{Fail}(\delta(y))\}$. 

Showing the equivalence between the coalgebraic and the original definitions of ready, respectively, failure semantics reduces to proving that

$$(\forall x \in X). \llbracket \{x\}\rrbracket = \varphi^\mathcal{T}_x.$$  \hspace{1cm} (6)

**Theorem 3.1.** Let $(X, \delta: X \to (\mathcal{P}_\omega X)^A)$ be an LTS. Then for all $x \in X$ and $w \in A^*$, $\llbracket \{x\}\rrbracket(w) = \varphi^\mathcal{T}_x(w)$.

**Proof.** For $I$ ranging over $\{\mathcal{R}, \mathcal{F}\}$, the proof is by induction on words $w \in A^*$. We provide the details for the case of ready semantics. A similar reasoning can be applied for failure semantics.

— **Base case.** $w = \varepsilon$. We have:

\[
\llbracket \{x\}\rrbracket(\varepsilon) = o(\{x\}) = \{ I(\delta(x)) \}
\]

$$\varphi^\mathcal{R}_x(\varepsilon) = \{ Z \subseteq A \mid x \xrightarrow{\varepsilon} y \land Z = I(\delta(y))\} = \{ I(\delta(x)) \}$$

— **Induction step.** Consider $w \in A^*$ and assume, for all $x \in X$, $\llbracket \{x\}\rrbracket(w) = \varphi^\mathcal{R}_x(w)$. We want to prove that $\llbracket \{x\}\rrbracket(aw) = \varphi^\mathcal{R}_x(aw)$, where $a \in A$.

\[
\llbracket \{x\}\rrbracket(aw) = \llbracket t(\{x\})(a)\rrbracket(w) = \bigcup_{x \xrightarrow{a} z} \llbracket \{z\}\rrbracket(aw) \upharpoonright \bigcup_{x \xrightarrow{a} z} \varphi^\mathcal{R}_x(aw)
\]

$$\varphi^\mathcal{R}_x(aw) = \{ Z \mid x \xrightarrow{aw} y \land Z = I(\delta(y))\}
= \{ Z \mid x \xrightarrow{a} z \land z \xrightarrow{w} y \land Z = I(\delta(y))\}
= \bigcup_{x \xrightarrow{a} z} \varphi^\mathcal{R}_x(aw) \quad \square
$$

**Example 3.1.** In what follows we illustrate the equivalence between the coalgebraic and the original definitions of ready semantics by means of an example. Consider the following LTS.

$$
\begin{array}{c}
 p_0 \\
 a \\
 p_1 \downarrow \\
 b \\
 a \\
 p_3 \downarrow \\
 d \\
 p_5
\end{array}
$$

We write $a^n$ to represent the action sequence $aa \ldots a$ of length $n \geq 1$, with $n \in \mathbb{N}$. The set of all ready pairs associated to $p_0$ is:

$$\mathcal{R}(p_0) = \{ (\varepsilon, \{a\}), (a^n, \{a\}), (a^n, \{b\}), (a^n b, \{c\}), (a^n b, \{d\}), (a^n b c \emptyset), (a^n b d, \emptyset) \mid n \geq 1 \}.$$  

We can construct a Moore automaton, for $S = \{p_0, p_1, \ldots, p_5\}$,

$$\mathcal{P}_\omega S, (a, t): \mathcal{P}_\omega \mathcal{P}_\omega S \to \mathcal{P}_\omega(\mathcal{P}_\omega A) \times (\mathcal{P}_\omega S)^A$$

by applying the generalized powerset construction on the LTS above. The automaton will have $2^6 = 64$ states. We depict the accessible part from state $\{p_0\}$, where the output sets are indicated by double arrows: The output sets of a state $Y$ of the Moore automaton in Fig. 3 is the set of actions associated to a certain state $y \in Y$ which can immediately be performed. For example, process $p_0$ in the original LTS above is ready to perform action
Let $Z$, whereas $p_1$ can immediately perform $b$. Therefore it holds that $o(\{p_0\}) = \{\{a\}\}$ and $o(\{p_0, p_1\}) = \{\{a\}, \{b\}\}$.

By simply looking at the automaton in Fig. 3, one can easily see that the set of action sequences $w \in A^*$ the state $\{p_0\}$ can execute, together with the corresponding possible next actions equals $R(p_0)$. Therefore, the automaton generated according to the generalized powerset construction captures the set of all ready pairs of the initial LTS.

**Example 3.2.** The last example considered in this section shows how the coalgebraic framework can be applied in order to reason on failure equivalence of LTS’s. (Checking ready equivalence complies to a similar approach.) Consider the following two systems.

\[
\begin{align*}
\{p_0\} & \Rightarrow \{\{a\}\} \\
\{p_0, p_1\} & \Rightarrow \{\{a\}, \{b\}\} \\
\emptyset & \Leftarrow \{p_1\} \\
\emptyset & \Rightarrow \{p_5\} \Rightarrow \emptyset
\end{align*}
\]

Fig. 3. Ready determinization when starting from $\{p_0\}$.

Let $Z = \{a_1, a_2, \ldots, a_n\}$ be the set of actions a process fails executing as a first step. For the simplicity of notation, we write $[a_1 a_2 \ldots a_n]$ to denote the set of all non-empty subsets $Z' \subseteq Z$. For example, if $Z = \{a_1, a_2\}$, then $[a_1 a_2]$ stands for $\{\{a_1\}, \{a_2\}, \{a_1, a_2\}\}$.

Note that $p_0$ and $q_0$ are $F$-equivalent, according to Definition 3.2, as they have the same sets of failure pairs:

\[
F(p_0) = F(q_0) = \{(ε, [def]), (b, [abcde f]), (c, [abcde f])\} \cup \{(a^n, [def]), (a^n, [bde]), (a^n b, [abcde f]), (a^n c, [abcde f]), (a^n c, [abcde f]), (a^n c, [abcde f]) | n \in \mathbb{N}, n \geq 1\}
\]

The same conclusion can be reached by checking behavioural equivalence of the two Moore automata generated according to the powerset construction, starting with $\{p_0\}$ and $\{q_0\}$. The fragments of the two automata starting from the states $\{p_0\}$ and $\{q_0\}$ are depicted in Fig. 4. The states $\{p_0\}$ and $\{q_0\}$ are Moore bisimilar, since the automata above are isomorphic.
3.2. (Complete) trace semantics

In this section we model coalgebraically trace and complete trace semantics. Similar to the previous section, we also show that the corresponding coalgebraic representations of these semantics are equivalent to their original definitions.

Consider an LTS \((X, \delta : X \to (\mathcal{P}_w X)^A))\). Trace semantics identifies states in \(X\) according to the set of words \(w \in A^*\) they can execute, whereas complete trace semantics identifies states \(x \in X\) based on their set of complete traces. A trace \(w \in A^*\) of \(x\) is complete if and only if \(x\) can perform \(w\) and reach a deadlock state \(y\) or, equivalently,

\[
(\exists y \in X). x \xrightarrow{w} y \land I(\delta(y)) = \emptyset.
\]

The difference between trace and complete semantics is that the latter enables an external observer to detect stagnation, or deadlock states of a system.

Formally, trace and complete trace equivalences are defined as follows.

**Definition 3.3 (\(T\)-equivalence (van Glabbeek 2001)).** Let \((X, \delta : X \to (\mathcal{P}_w X)^A))\) be an LTS and \(x, y \in X\) two states. States \(x\) and \(y\) are trace equivalent \((T\)-equivalent\) if and only if \(T(x) = T(y)\), where

\[
T(x) = \{ w \in A^* \mid \exists x' \in X. x \xrightarrow{w} x' \}.
\]

**Definition 3.4 (\(CT\)-equivalence (Aceto, Fokkink & Verhoef 1999)).** Let \((X, \delta : X \to (\mathcal{P}_w X)^A))\) be an LTS and \(x, y \in X\) two states. States \(x\) and \(y\) are complete trace equivalent \((CT\)-equivalent\) if and only if \(CT(x) = CT(y)\), where

\[
CT(x) = \{ w \in A^* \mid \exists x' \in X. x \xrightarrow{w} x' \land I(\delta(x')) = \emptyset \}.
\]

In what follows we instantiate the constituents of Fig. 2 in order to provide the associated coalgebraic modellings.

For \(\mathcal{I} \in \{T, CT\}\), the output function \(\overline{\sigma}_\mathcal{I} : X \to 2\) is:

\[
\overline{\sigma}_T(x) = 1 \quad \overline{\sigma}_{CT}(x) = \begin{cases} 1 & \text{if } I(\delta(x)) = \emptyset \\ 0 & \text{otherwise} \end{cases}
\]
Note that, for trace semantics, one does not distinguish between traces and complete traces. Intuitively, all states are accepting, so they have the same observable behaviour (i.e., $\sigma_T(\varphi) = 1$), no matter the transitions they perform. On the other hand, complete trace semantics distinguishes between deadlock states and states that can still execute actions $a \in A$.

Consider, for example, the following LTS:

$$
\begin{array}{c}
P_1 \\
\downarrow^a\\
P_0 \\
\downarrow^b\\
P_2
\end{array}
$$

Observe that $(ab)^*a$ is a complete trace of $p_0$, as

$$p_0 \xrightarrow{a} p_2 \xrightarrow{b} p_0 \xrightarrow{a} p_2 \xrightarrow{b} \ldots \xrightarrow{b} p_0 \xrightarrow{a} p_1$$

where $p_1$ cannot perform any further action.

The above behaviour, described in terms of transitions between states of the Moore automaton derived according to the generalized powerset construction, can be depicted as follows:

$$
\{ p_0 \} \xrightarrow{a} \{ p_1, p_2 \} \xrightarrow{b} \{ p_0 \} \xrightarrow{a} \{ p_1, p_2 \} \xrightarrow{b} \ldots \xrightarrow{b} \{ p_0 \} \xrightarrow{a} \{ p_1, p_2 \}
$$

where $p_1$ is a deadlock state and $p_2$ is not.

Intuitively, we can state that $(ab)^*a$ is a complete trace of $\{ p_0 \}$, as the deadlock state $p_2 \in \{ p_1, p_2 \}$ can be reached from $\{ p_0 \}$ by performing $(ab)^*a$ (see (8)).

Therefore, given $Y_1, Y_2 \subseteq X$ and $w \in A^*$ such that $Y_1 \xrightarrow{w} Y_2$, we observe that $w$ is a complete trace of $Y_1$ whenever there exists a deadlock state $y \in Y_2$. Otherwise, $w$ is not a complete trace of $Y_1$.

In the coalgebraic modelling, the above observations regarding (non)stagnating states appear in the definition of the output function $o: P_\omega(X) \rightarrow 2$. Note that, for example, $o(\{ p_1, p_2 \}) = 1$ and $o(\{ p_0 \}) = 0$ for the case of complete trace equivalence, as $p_1$ is a deadlock state and $p_0$ is not. For trace semantics we have $o(\{ p_1, p_2 \}) = o(\{ p_0 \}) = 1$.

Here, $B_I = 2$ and the final Moore coalgebra in Fig. 2 is the set of languages $2^A^*$ over $A$ (and the transition structure $\langle \epsilon, (-)\rangle$ is simply given by Brzozowski derivatives).

Therefore, we can state that the map into the final coalgebra associates to each state $Y \in P_\omega X$ the set of all traces corresponding to states $y \in Y$, namely, the language:

$$L = \bigcup_{y \in Y} \{ w \in A^* \mid (\exists y' \in X). y \xrightarrow{w} y' \}.$$

The set $P(A^*)$ is isomorphic to the set of functions $2^A^*$ which enables us to represent the set $I(x)$ in terms its characteristic function $\varphi^T_x: A^* \rightarrow 2$ defined, for $I \in \{ T, CT \}$, $w \in A^*$, as follows:

$$
\varphi^T_x(w) = 1 \text{ if } \exists y \in X. x \xrightarrow{w} y \\
\varphi^{CT}_x(w) = \begin{cases} 1 & \text{if } \exists y \in X. x \xrightarrow{w} y \land I(\delta(y)) = \emptyset \\ 0 & \text{otherwise.} \end{cases}
$$

Proving the equivalence between the coalgebraic and the classic definition of (complete) trace semantics reduces to showing that

$$(\forall x \in X). \|\{x\}\| = \varphi^T_x.$$

(9)
Theorem 3.2. Let \((X, \delta : X \to (\mathcal{P}_\omega X)^4)\) be an LTS. Then for all \(x \in X\) and \(w \in A^*\), 
\[
\|\{x\}\|_x(w) = \phi^x(w).
\]

Proof. The proof is by induction on words \(w \in A^*\) (similar to the proof of Theorem 3.1).

Example 3.3. Consider the following two LTS’s:

\[
\begin{array}{c}
\text{w}_0 \xrightarrow{a} \text{w}_0 \\
\text{w}_0 \xrightarrow{a} \text{w}_0
\end{array}
\]

Observe that \(w_0\) and \(w_0'\) are trace equivalent (according to Definition 3.3), as they output the same sets of traces

\[
T(w_0) = T(w_0') = \{\varepsilon\} \cup \{a^n \mid n \in \mathbb{N}, n \geq 1\}
\]

but they are not complete trace equivalent (according to Definition 3.4), as \(w_0'\) can never reach a deadlock state, whereas \(w_0\) can reach the stagnating state \(w_1\).

The complete trace determinization contains the sub-automata starting from states \(\{w_0\}\) and \(\{w_0'\}\) depicted in Fig. 5: States \(\{w_0\}\) and \(\{w_0'\}\) are not behaviourally equivalent,

\[
0 \not\sim \{w_0\} \xrightarrow{a} \{w_0, w_1\} \not\sim 1 \quad 0 \not\sim \{w_0'\} \xrightarrow{a}
\]

Fig. 5. Complete trace determinization when starting from \(\{w_0\}, \{w_0'\}\).

since \(\{w_0, w_1\}\) outputs 1, whereas \(\{w_0'\}\) never reaches a state with this output. Hence, as expected, we will never be able to build a bisimulation containing states \(\{w_0\}\) and \(\{w_0'\}\).

On the other hand, in the setting of trace semantics, the determinized (Moore) automata associated to \(w_0\) and \(w_0'\), respectively, are similar to those depicted in Fig. 5, with the difference that now all their states output value 1. This makes the aforementioned automata bisimilar, hence providing a “yes” answer w.r.t. \(T\)-equivalence of \(w_0\) and \(w_0'\), as anticipated.

3.3. Possible-futures semantics

In what follows we provide a coalgebraic modelling of possible-futures semantics and show that it coincides with the original definition in (van Glabbeek 2001). We also give an example on how the generalized powerset construction and Moore bisimulations can be used in order to reason on possible-futures equivalence.

Let \((X, \delta : X \to (\mathcal{P}_\omega X)^4)\) be an LTS. A possible future of \(x \in X\) is a pair \(\langle w, T \rangle \in A^* \times \mathcal{P}(A^*)\) such that \(x \xrightarrow{w} y\) and \(T = T(y)\) (where \(T(y)\) is the set of traces of \(y\), as in Section 3.2).

Possible-futures semantics identifies states that can trigger the same sets of traces \(w \in A^*\) and moreover, by executing such \(w\), they reach trace-equivalent states.

Definition 3.5 (\(\mathcal{P}\mathcal{F}\)-equivalence (van Glabbeek 2001)). Let \((X, \delta : X \to (\mathcal{P}_\omega X)^4)\)
be an LTS and \( x, y \in X \) two states. States \( x \) and \( y \) are possible-futures equivalent (\( \mathcal{PF} \)-equivalent) if and only if \( \mathcal{PF}(x) = \mathcal{PF}(y) \), where

\[
\mathcal{PF}(x) = \{ \langle w, T \rangle \in A^* \times \mathcal{P}(A^*) \mid \exists x' \in X, x \xrightarrow{w} x' \land T = T(x') \}.
\]

The ingredients of Fig. 2 are instantiated as follows.

The output function \( \varphi_{\mathcal{PF}} : X \to \mathcal{P}(\mathcal{P}A^*) \), which refers to the set of traces enabled by states \( x \in X \) of the LTS, is defined as

\[
\varphi_{\mathcal{PF}}(x) = \{ \mathcal{T}(x) \}.
\]

Here, \( B_x = B_{\mathcal{PF}} = \mathcal{P}(\mathcal{P}A^*) \) and the behaviour of a state \( x \in X \) in the final coalgebra is given in terms of a function \( \llbracket \{ x \} \rrbracket : A^* \to \mathcal{P}(\mathcal{P}A^*)^A \), which, intuitively, for each \( w \in A^* \) returns the set of sets \( T_y \) of traces corresponding to states \( y \in X \) such that \( x \xrightarrow{w} y \).

Next we want to show that for each \( x \in X \), \( \llbracket \{ x \} \rrbracket \) and \( \mathcal{PF}(x) \) coincide.

First we choose to equivalently represent \( \mathcal{PF}(x) \in \mathcal{P}(\mathcal{P}A^*) \) – the set of all possible futures of a state \( x \in X \) – in terms of \( \varphi_{\mathcal{PF}}^x \in (\mathcal{P}(\mathcal{P}A^*))^A \), where

\[
\varphi_{\mathcal{PF}}^x(w) = \{ \mathcal{T}(y) \mid x \xrightarrow{w} y \},
\]

Showing the equivalence between the coalgebraic and the original definition of possible-futures semantics reduces to proving that

\[
(\forall x \in X). \llbracket \{ x \} \rrbracket = \varphi_{\mathcal{PF}}^x.
\]

**Theorem 3.3.** Let \((X, \delta : X \to (\mathcal{P}A^*)^A)\) be an LTS. Then for all \( x \in X \) and \( w \in A^* \),

\[
\llbracket \{ x \} \rrbracket (w) = \varphi_{\mathcal{PF}}^x(w).
\]

**Proof.** The proof is by induction on \( w \in A^* \) (similar to the proof of Theorem 3.1). \( \square \)

**Example 3.4.** Consider the following LTS’s.

\[
\begin{array}{cccccccc}
 & & & & a & & a & \\
 & & & & p_0 & & p_1 & \\
b & & a & & p_a & & a & \\
b & & p_1 & & p_2 & & a & \\
a & & a & & p_3 & & a & \\
b & & p_4 & & p_5 & & a & \\
a & & a & & p_6 & & a & \\
b & & p_7 & & b & & a & \\
b & & q_1 & & q_1 & & a & \\
a & & a & & q_2 & & a & \\
b & & q_3 & & q_3 & & a & \\
a & & a & & q_4 & & a & \\
b & & q_5 & & q_5 & & a & \\
a & & a & & q_6 & & a & \\
b & & q_7 & & q_7 & & a & \\
q_8 & & q_8 & & q_8 & & a & \\
q_9 & & q_9 & & q_9 & & a & \\
q_10 & & q_10 & & q_10 & & a & \\
q_11 & & q_11 & & q_11 & & a & \\
q_12 & & q_12 & & q_12 & & a & \\
q_13 & & q_13 & & q_13 & & a & \\
q_14 & & q_14 & & q_14 & & a & \\
q_15 & & q_15 & & q_15 & & a & \\
q_16 & & q_16 & & q_16 & & a & \\
q_17 & & q_17 & & q_17 & & a & \\
p_3 & & p_3 & & p_3 & & p_3 & \\
p_8 & & p_8 & & p_8 & & p_8 & \\
p_9 & & p_9 & & p_9 & & p_9 & \\
p_{10} & & p_{10} & & p_{10} & & p_{10} & \\
p_{11} & & p_{11} & & p_{11} & & p_{11} & \\
p_{12} & & p_{12} & & p_{12} & & p_{12} & \\
p_{13} & & p_{13} & & p_{13} & & p_{13} & \\
p_{14} & & p_{14} & & p_{14} & & p_{14} & \\
p_{15} & & p_{15} & & p_{15} & & p_{15} & \\
p_{16} & & p_{16} & & p_{16} & & p_{16} & \\
p_{17} & & p_{17} & & p_{17} & & p_{17} & \\
\end{array}
\]

Note that \( p_0 \) and \( q_0 \) are possible-futures equivalent, as the traces both can follow are sequences \( w \in \{ a, ab, aa, aab, aac, aacd, aace \} \) and moreover, by triggering the same \( w \) they reach states with equal sets of traces. The equivalence between \( p_0 \) and \( q_0 \) can be formally captured in terms of a bisimulation relation \( R \) on the associated Moore automata (generated according to the generalized powerset construction) depicted in Fig. 6, where

\[
R = \{ \{(p_0), \{q_0\}\}, \{(p_1, p_2), \{q_1, q_2\}\}, \{(p_3), \{q_7\}\}, \{(p_8, p_{13}), \{q_8, q_{13}\}\}, \{(p_5, p_5, p_6, p_7), \{q_3, q_4, q_5, q_6\}\}, \{(p_9, p_{10}, p_{11}, p_{12}), \{q_9, q_{10}, q_{11}, q_{12}\}\}, \{(p_{14}, p_{16}), \{q_{14}, q_{16}\}\}, \{(p_{15}, p_{17}), \{q_{15}, q_{17}\}\}\}.
\]
Bonchi, Bonsangue, Caltais, Rutten, Silva

\[ \{p_0\} \cong \{T(p_0)\} \quad \{q_0\} \cong \{T(q_0)\} \]

\[ \{\} \leftrightarrow \{p_8, p_{13}\} \quad \{p_1, p_2\} \cong \{T(p_1), T(p_2)\} \quad \{\} \leftrightarrow \{q_8, q_{13}\} \quad \{q_1, q_2\} \cong \{T(q_1), T(q_2)\} \]

\[ o_1 \cong \{p_4, p_5, p_6, p_7\} \quad \{p_3\} \cong \{\} \quad o_1' \cong \{q_3, q_4, q_5, q_6\} \quad \{q_7\} \cong \{\} \]

\[ o_2 \cong \{p_9, p_{10}, p_{11}, p_{12}\} \quad o_2' \cong \{q_9, q_{10}, q_{11}, q_{12}\} \]

\[ \{\} \cong \{p_{14}, p_{16}\} \quad \{p_{15}, p_{17}\} \cong \{\} \quad \{\} \cong \{q_{14}, q_{16}\} \quad \{q_{15}, q_{17}\} \cong \{\} \]

Fig. 6. Possible-futures determinization when starting from \{p_0\}, \{q_0\}.

\[ o_1 = \{T(p_4), T(p_5), T(p_6), T(p_7)\}, o_2 = \{T(p_9), T(p_{10}), T(p_{11}), T(p_{12})\}, o_1' = \{T(q_3), T(q_4), T(q_5), T(q_6)\}, o_2' = \{T(q_9), T(q_{10}), T(q_{11}), T(q_{12})\}. \]

It is easy to check that \( R \) is a bisimulation, since both automata in Fig. 6 are isomorphic. (Note that equality of the outputs – which are sets of traces – can be established using the framework introduced in Section 3.2.)

3.4. Ready and failure trace semantics

In this section we provide a coalgebraic modelling of ready and failure trace semantics by employing the generalized powerset construction. Similarly to the other semantics tackled so far, we show a) that the coalgebraic representation coincides with the original definition in (van Glabbeek 2001) and b) how to apply the coalgebraic machinery in order to reason on the corresponding equivalences.

Intuitively, ready trace semantics identifies two states if and only if they can follow the same traces \( w \), and moreover, the corresponding (pairwise-taken) states determined by such \( w \)’s have equivalent one-step behaviours. Failure trace semantics identifies states that can trigger the same traces \( w \), and moreover, the (pairwise-taken) intermediate states occurring during the execution of a such \( w \) fail triggering the same (sets of) actions. Formally, the associated definitions are as follows:

**Definition 3.6 (RT-equivalence (van Glabbeek 2001)).** Let \( (X, \delta : X \to (\mathcal{P}_\omega X)^A) \) be an LTS and \( x, y \in X \) two states. States \( x \) and \( y \) are **ready trace equivalent** (RT-equivalent) if and only if \( RT(x) = RT(y) \), where

\[ RT(x) = \{ \ I_0a_1I_1a_2 \ldots a_nI_n \in \mathcal{P}_\omega(A) \times (A \times \mathcal{P}_\omega(A))^* \mid \\
(\exists x_1, \ldots, x_n \in X). x = x_0 \xrightarrow{a_1} x_1 \xrightarrow{a_2} \ldots \xrightarrow{a_n} x_n \land \\
(\forall i = 0, \ldots, n). I_i = I(\delta(x_i)) \} . \]

We call an element of \( RT(x) \) a **ready trace** of \( x \).

**Definition 3.7 (FT-equivalence).** Let \( (X, \delta : X \to (\mathcal{P}_\omega X)^A) \) be an LTS and \( x, y \in X \) two states. States \( x \) and \( y \) are **failure trace equivalent** (FT-equivalent) if and only if
A coalgebraic view on decorated traces

\[ FT(x) = FT(y), \]

where

\[ FT(x) = \{ F_0 a_1 F_1 a_2 \ldots a_n F_n \in P_\omega(A) \times (A \times P_\omega(A))^* \mid \exists x_1, \ldots, x_n \in X : x = x_0 \xrightarrow{a_1} x_1 \xrightarrow{a_2} \ldots \xrightarrow{a_n} x_n \wedge F_i \in \text{Fail}(\delta(x_i)) \}. \]

We call an element of \( FT(x) \) a failure trace of \( x \).

In order to model these two equivalences coalgebraically we will have to apply the generalized powerset construction, from Fig. 2, not only by adding the output function but also by changing the transitions of the LTS.

In particular, we have to add to transitions of shape \( x \xrightarrow{a} y \) information regarding the sets of actions ready to be triggered by \( x \). In the new LTS we consider transitions of shape \( x \xrightarrow{(a,I(\delta(x)))} y \) therefore enabling the construction of Moore automata “collecting” states that have been reached not only via one-step transitions labelled the same, but also from processes sharing the same initial behaviour. (Note that \( F \in \text{Fail}(\delta(x)) \) whenever \( F \subseteq A - I(\delta(x)) \).)

We apply the generalized powerset construction to the decorated LTS:

\[ X \xrightarrow{(\sigma, \delta)} P_\omega(P_\omega(A)) \times P_\omega(X)^{A \times P_\omega(A)} \]

where \( \delta \) is defined by first computing the set \( I \) and then appending it to every successor of a state by using the strength of powerset:

\[ \delta = X \xrightarrow{\delta} P_\omega(X)^A \xrightarrow{(I, \text{id})} P_\omega(A) \times P_\omega(X)^A \xrightarrow{\text{st}} P_\omega(P_\omega(A) \times X)^A \rightarrow P_\omega(X)^{A \times P_\omega(A)} \]

For \( I \in \{RT, FT\} \), the output function \( \bar{\sigma}_I \) provides information with respect to the actions ready, respectively, failed to be triggered by a state \( x \in X \) as a first step:

\( \bar{\sigma}_{RT}(x) = \{ I(\delta(x)) \} \quad \bar{\sigma}_{FT}(x) = \text{Fail}(\delta(x)). \)

We need to show that for \( x_0 \in X \), there is a one-to-one correspondence between \( \llbracket \{x_0\} \rrbracket \) and \( \mathcal{I}(x_0) \). Intuitively, for ready trace semantics, for example, each behaviour

\[ \llbracket \{x_0\}\rrbracket(\Bar{w}) = \{ Z_n \mid x_a^w x_j \}, \quad \text{with } \Bar{w} = \langle a_1, Z_0 \rangle \ldots \langle a_n, Z_{n-1} \rangle \in (A \times P_\omega(A))^* \quad \text{and } w = a_1 \ldots a_n \in A^* \]

corresponds to a set of sequences of shape

\[ Z_0 a_1 Z_1 a_2 \ldots Z_{n-1} a_n Z_n^i \in \mathcal{I}(x_0). \]

Given \( x \in X \), for \( I \in \{RT, FT\} \), we again represent \( \mathcal{I}(x) \in \mathcal{P}(P_\omega(A) \times (A \times P_\omega(A))^*) \) by a function \( \varphi^I_x \):

\[ \varphi^\mathcal{RT}_x(\Bar{w}) = \{ Z \subseteq A \mid x \xrightarrow{\Bar{w}} y \wedge Z = I(\delta(y)) \} \]

\[ \varphi^\mathcal{FT}_x(\Bar{w}) = \{ Z \subseteq A \mid x \xrightarrow{\Bar{w}} y \wedge Z \in \text{Fail}(\delta(y)) \} \]

Showing the equivalence between the coalgebraic and the original definition of ready and failure trace semantics consists in proving that

\[ (\forall x \in X).\llbracket \{x\} \rrbracket = \varphi^\mathcal{I}_x. \quad (11) \]
Theorem 3.4. Let \((X, \delta : X \to (\mathcal{P}_\omega X)^A)\) be an LTS. Then for all \(x \in X\) and \(\bar{w} \in (A \times \mathcal{P}_\omega(A))^\omega\), \(\|x\|\bar{w} = \varphi_x^\omega(\bar{w})\).

Proof. The proof follows by induction on words \(w \in (A \times \mathcal{P}_\omega(A))^\omega\) (similar to the proof of Theorem 3.1).

Example 3.5. Consider the following two systems:

![Diagram of two Moore automata]

Note that they are not ready trace equivalent as, for example, \(\{a\}a\{c, f\}c\{e\}\) is a ready trace of \(p_0\) but not of \(q_0\). Moreover, they are not failure trace equivalent as, for example, \(\{b, c, d, e, f\}a\{a, d, e, f\}c\{a, b, c, e, f\}d\{a, b, c, d, e, f\}\) is a failure trace of \(p_0\) but not of \(q_0\).

It is easy to check that by taking exactly the generalized powerset construction (starting with \(\{p_0\}, \{q_0\}\)) without changing the transition function, as in Section 3.1, one gets two bisimilar Moore automata (for both the case of ready and failure trace equivalence). This would indicate that the initial LTS’s are behavioural equivalent (which is not the case for ready and failure trace!).

The change in the transition function generates the automata (with labels in \(A \times \mathcal{P}_\omega(A)\)) in Fig. 7. Then, for both semantics studied in this section, the determinization derives the two Moore automata in Fig. 8.

For ready trace semantics it holds that:

\[
\begin{align*}
o_0 &= \overline{\sigma}_0 = \{\{a\}\} & o_{12} &= \overline{\sigma}_{12} = \{\{b, c\}, \{c, f\}\} & o_4 &= \overline{\sigma}_5 = \{\{d\}\} & o_5 &= \overline{\sigma}_4 = \{\{e\}\} \\
o_3 &= o_6 = o_7 = o_8 = \overline{\sigma}_3 = \overline{\sigma}_6 = \overline{\sigma}_7 = \overline{\sigma}_8 = \emptyset.
\end{align*}
\]

Hence, the systems in Fig. 8 are not bisimilar as, for example, both states \(\{p_4\}\) and \(\{q_4\}\) can be reached via transitions labelled the same, but they output different sets of ready actions – namely \(\{\{d\}\}\) and \(\{\{e\}\}\), respectively. Therefore, we conclude that \(p_0\) and \(q_0\) are not ready trace equivalent.

Similarly, for failure trace we have:

\[
\begin{align*}
o_0 &= \overline{\sigma}_0 = [bcdef] & o_{12} &= \overline{\sigma}_{12} = [abcdef] \cup [abde] & o_4 &= \overline{\sigma}_5 = [abcef] & o_5 &= \overline{\sigma}_4 = [abcdf] \\
o_3 &= o_6 = o_7 = o_8 = \overline{\sigma}_3 = \overline{\sigma}_6 = \overline{\sigma}_7 = \overline{\sigma}_8 = [abcdef].
\end{align*}
\]

As before, the automata in Fig. 8 are not bisimilar as, for example, both \(\{p_4\}\) and \(\{q_4\}\) are reached via transitions labelled the same, but have different outputs. Therefore we conclude that \(p_0\) and \(q_0\) are not failure trace equivalent.

The purpose of changing the transition labels with sets of ready actions is to collect in a Moore state only states of the initial LTS’s that have been reached from “parents” with the same one-step (initial) behaviour. Or dually, to distinguish between states that have “parents” ready, respectively, failing to trigger different sets of actions. This way one avoids the unfortunate situation of encapsulating, for example, the states \(p_4, p_5,\)
respectively \( q_4, q_5 \), fact which eventually would lead to providing a positive answer with respect to both ready and failure trace equivalence of \( p_0 \) and \( q_0 \).

In other words, the change in the transition function is needed in order to guarantee that whenever two states of an LTS are ready/failure trace equivalent, the (pairwise-taken) states determined by the executions of a given trace have the same initial behaviour.

4. Decorated trace semantics for GPS’s via determinization

In this section we show how the generalized powerset construction for coalgebras \( f : X \to FT(X) \) for a functor \( F \) and a monad \( T \) in (3) can be instantiated in order to provide coalgebraic modellings of decorated trace semantics for generative probabilistic systems (GPS’s). More explicitly, we show how the determinization procedure can be applied in order to derive coalgebraic representations of ready, (maximal) failure and (maximal) trace semantics, equivalent to their standard definitions in (Jou & Smolka 1990).

A GPS is similar to an LTS, but each transition is labelled by both an action and a probability \( p \). More precisely, the transition dynamics is given by a probabilistic transition function \( \mu : X \times A \times X \to [0, 1] \) satisfying for all \( x \in X \)

\[
\sum_{a \in A} \mu(x, a, y) \leq 1, \quad (12)
\]

where \( X \) is the state space and \( A \) is the alphabet of actions. For simplicity, we write
\(\mu\) in lieu of \(\mu(x, a, y)\) and we will use the notation \(x \xrightarrow{\alpha|v} y\) for \(\mu(x, y) = v\). We extend \(\mu\) to words \(w \in A^*\):

\[
\mu_{\epsilon}(x, y) = \begin{cases} 
1 & \text{if } x = y \\
0 & \text{if } x \neq y
\end{cases} \quad \mu_{aw}(x, y) = \sum_{x' \in X} \mu_{a}(x, x') \times \mu_{w}(x', y)
\]

Intuitively, \(\mu_w(x, y)\) represents the sum of the probabilities associated to all traces \(w\) from \(x\) to \(y\). Moreover, we write \(\mu_{0}(x, 0) = 1 - \sum_{a \in A} \mu(x, a, y)\) for the probability of \(x\) to terminate, where \(0\) is a special symbol not in \(A\), called the zero action, and \(0\) is the (deadlock-like) zero process whose only transition is \(\mu_{0}(0, 0) = 1\).

Similarly to the case of LTS’s, the set of initial actions that can be triggered (with a probability greater than 0) from \(x \in X\) is given by

\[I(x) = \{a \in A \mid (\exists y \in X). \mu_a(x, y) > 0\},\]

whereas failure sets \(Z \in \mathcal{P}_\omega A\) satisfy the condition \(Z \cap I(x) = \emptyset\). We write \(\text{Fail}(x)\) to represent the set of all failure sets of \(x\).

The decorated trace semantics for GPS’s considered in this paper can be intuitively described as follows. Given two states \(x, y \in X\), we say that \(x\) and \(y\) are equivalent whenever traces \(w \in A^*\)

— lead, with the same probability, \(x\) and \(y\) to processes that trigger (respectively, fail to execute) as a first step the same sets of actions, for the case of ready (respectively, failure) semantics. Note that maximal failure semantics takes into consideration only the largest sets of failure actions (i.e., \(A - I(x), A - I(y)\)).

— can be executed with the same probability from both \(x\) and \(y\), for the case of trace semantics and, moreover, lead \(x\) and \(y\) to processes that have the same probability to terminate, for the case of maximal trace semantics.

For the coalgebraic modelling of the aforementioned semantics, we will model GPS’s as coalgebras \((X, \delta: X \to (\mathcal{D}_\omega(X))^A)\) by setting \(\delta(x)(a)(y) = \mu_{a}(x, y)\). To these, we associate decorated GPS’s

\[(X, (\pi_T, \delta): X \to B_T \times (\mathcal{D}_\omega(X))^A)\]

“parameterized” by \(T\), depending on the semantics under consideration.

Decorated GPS’s can be determinized according to the generalized powerset construction as illustrated in Fig. 9, where \(T\) is instantiated with the probability distribution monad \((\mathcal{D}_\omega, \mu, \eta)\), as defined in Section 2, and \(\mathcal{F}\) is \(B_T \times (-)^A\). Moreover, for each of the semantics of interest the observations set \(B_T\) has to carry a \(\mathcal{D}_\omega\)-algebra structure, or,

\(^1\) Note that the coalgebraic type directly corresponds to reactive systems (Bartels, Sokolova & de Vink 2004). The embedding of generative into reactive is injective and poses no problems semantic-wise. In the sequel, when we write “Let \((X, \delta: X \to (\mathcal{D}_\omega(X))^A)\) be a GPS” we implicitly mean a coalgebra of this type originating from a GPS defined by a probabilistic function \(\mu: X \times A \times X \to [0, 1]\) as in (12).
equivalently, there has to exist a morphism \( h_I \) such that \((B_I, h_I : \mathcal{D}_\omega(B_I) \to B_I)\) is a \( \mathcal{D}_\omega \)-algebra.

\[
\begin{array}{c}
X \xrightarrow{\eta} \mathcal{D}_\omega(X) \xrightarrow{\mathcal{D}_\omega(B_I)} (B_I)^{A^*} \\
\downarrow \quad (\sigma_I, \delta) \quad \downarrow (\eta, \epsilon) \\
B_I \times (\mathcal{D}_\omega(X))^A \xrightarrow{\text{id}_{B_I} \times \mathcal{D}_\omega(B_I)} B_I \times ((B_I)^{A^*})^A
\end{array}
\]

\[
o = h_I \circ \mathcal{D}_\omega(\bar{\sigma}_I) \\
t(\varphi)(a)(y) = \sum_{x \in \text{supp}(\varphi)} \delta(x)(a)(y) \times \varphi(x) \\
[\varphi](e) = \alpha(\varphi) \\
[\varphi](aw) = [t(\varphi)(a)](w)
\]

Fig. 9. The powerset construction for decorated GPS’s.

The ingredients \( \bar{\sigma}_I, B_I \) and \( h_I \) of Fig. 9 are explicitly defined in the subsequent sections for each of the coalgebraic decorated trace semantics. The latter are also proven to be equivalent with their corresponding definitions in (Jou & Smolka 1990).

4.1. Ready and (maximal) failure semantics

In this section we provide the detailed coalgebraic modelling of ready and (maximal) failure semantics and show the equivalence with their counterparts defined in (Jou & Smolka 1990), as follows:

**Definition 4.1 (Ready equivalence (Jou & Smolka 1990)).** The ready function \( R_p : X \to ((A^* \times \mathcal{P}_\omega A) \to [0, 1]) \) is given by

\[
R_p(x)((w, I)) = \sum_{I = I(y)} \mu_w(x, y).
\]

We say that \( x, x' \in X \) are ready equivalent whenever \( R_p(x) = R_p(x') \).

**Definition 4.2 (Failure equivalence (Jou & Smolka 1990)).** The failure function \( F_p : X \to ((A^* \times \mathcal{P}_\omega A) \to [0, 1]) \) is given by

\[
F_p(x)((w, Z)) = \sum_{Z \cap I(y) = \emptyset} \mu_w(x, y).
\]

We say that \( x, x' \in X \) are failure equivalent whenever \( F_p(x) = F_p(x') \).

**Definition 4.3 (Maximal failure equivalence (Jou & Smolka 1990)).** The maximal failure function \( MF_p : X \to ((A^* \times \mathcal{P}_\omega A) \to [0, 1]) \) is given by

\[
MF_p(x)((w, Z)) = \sum_{Z = A - I(y)} \mu_w(x, y).
\]

We say that \( x, x' \in X \) are maximal failure equivalent whenever \( MF_p(x) = MF_p(x') \).

Intuition: ready and (maximal) failure semantics, respectively, identify states which have the same probability of reaching processes sharing the same sets of ready actions \( I \),
or (maximal) sets of failure actions \( Z \), respectively, by executing the same traces \( w \in A^* \). Consequently, appropriate modelings in the coalgebraic setting should capture sets of traces \( w \), together with some notion of observations based on execution probabilities of such \( w \)'s and sets of ready/(maximal) failure actions.

As a first step we define \( B_I \), the observation set in Fig. 9, as \([0, 1]^{p_\omega(A)}\) for ready, failure and maximal failure semantics (for which, for consistency of notation, \( I \) will be instantiated with \( R_p, F_p \) and \( MF_p \), respectively).

The associated “decorating” functions \( \sigma_I : X \to [0, 1]^{p_\omega(A)} \) are defined for \( x \in X \) as:

for \( I \in \{ R_p, F_p, MF_p \} \), the output function \( o = h_I \circ \sigma_I \) is explicitly defined, for \( \varphi \in \mathcal{D}_\omega(X) \), as:

This enables the modelling of the behaviour of GPS’s in terms of (final) Moore machines with state space in \((B_I)^{A^*}\) and observations in \( B_I \). More explicitly, given a GPS \((X, \delta)\), the decorated trace behaviour of \( x \in X \) is represented in the coalgebraic setting by \([\eta(x)] \in (B_I)^{A^*} = ([0, 1]^{p_\omega(A)})^{A^*} \cong [0, 1]^{A^* \times p_\omega(A)} \), precisely the type of the functions in Definitions 4.1–4.3. This paves the way for reasoning on ready and (maximal) failure equivalence by coinduction, in terms of Moore bisimulations.

Example 4.1. Consider, for example, the following GPS’s:
States $p'$ and $u'$ are ready equivalent, as their corresponding ready functions in Definition 4.1 are equal:

\[
\begin{align*}
\mathcal{R}_p(p')(\varepsilon, \emptyset) &= 0 & \mathcal{R}_p(p'(\varepsilon, \{a\}) &= 1 & \mathcal{R}_p(p'(a, \emptyset) &= 0 & \mathcal{R}_p(p'(aa, \{a\}) &= 0 \\
\mathcal{R}_p(u')(\varepsilon, \emptyset) &= 0 & \mathcal{R}_p(u'(\varepsilon, \{a\}) &= 1 & \mathcal{R}_p(u'(a, \emptyset) &= 0 & \mathcal{R}_p(u'(aa, \{a\}) &= 0 \\
\mathcal{R}_p(p'(a, \{a\}) &= \mu_a(p', q') + \mu_a(p', r') = x + (1 - x) = 1 \\
\mathcal{R}_p(p'(aa, \emptyset) &= \mu_{aa}(p', s') + \mu_{aa}(p', t') = x \times 1 + (1 - x) \times 1 = 1 \\
\mathcal{R}_p(u'(a, \{a\}) &= \mu_a(u', v') = 1 \\
\mathcal{R}_p(u'(aa, \emptyset) &= \mu_{aa}(u', w') + \mu_{aa}(u', w'' = 1 \times y + 1 \times (1 - y) = 1
\end{align*}
\]

Intuitively, $\mathcal{R}_p(p'(\varepsilon, \emptyset) = 0$ states that from $p'$, by executing the empty trace $\varepsilon$, the probability to reach states that cannot further trigger any action is 0. This is indeed the case, as $p'$ can always fire $a$ as a first step. Similarly, $\mathcal{R}_p(u'(a, \{a\}) = 1$ states that the probability of performing $a$ from $u'$ and reaching states with the ready set $\{a\}$ is 1. This because $u' \xrightarrow{a[1]} v'$ and $I(v') = \{a\}$.

The same answer w.r.t. the ready equivalence of $p'$ and $u'$ is obtained by applying the coalgebraic framework. As illustrated below, the corresponding Moore automata derived starting from $p'$ and $u'$, respectively, are bisimilar; they have the same branching structure and equal outputs:

\[
\begin{align*}
p': & & u': \\
\varphi_1 & \xrightarrow{a} & \varphi_2 & \xrightarrow{a} & \varphi_3 & \xrightarrow{a} & \varphi_3 & \xrightarrow{a} & \varphi_3 \\
o_{\varphi_1} & \downarrow & o_{\varphi_2} & \downarrow & o_{\varphi_3} & \downarrow & o_{\varphi_3} & \downarrow & o_{\varphi_3} \\
o_{\varphi_1} & \downarrow & o_{\varphi_2} & \downarrow & o_{\varphi_3} & \downarrow & o_{\varphi_3} & \downarrow & o_{\varphi_3}
\end{align*}
\]

The state spaces of the aforementioned Moore machines consist of the functions:

\[
\begin{align*}
\varphi_1 &= \eta(p') = \{p' \rightarrow 1, q' \rightarrow 0, r' \rightarrow 0, s' \rightarrow 0, t' \rightarrow 0\} \\
\varphi_2 &= \{p' \rightarrow 0, q' \rightarrow x, r' \rightarrow 1 - x, s' \rightarrow 0, t' \rightarrow 0\} \\
\varphi_3 &= \{p' \rightarrow 0, q' \rightarrow 0, r' \rightarrow 0, s' \rightarrow 1, t' \rightarrow 1\} \\
\alpha_1 &= \eta(u') = \{u' \rightarrow 1, v' \rightarrow 0, w' \rightarrow 0, w'' \rightarrow 0\} \\
\alpha_2 &= \{u' \rightarrow 0, v' \rightarrow 0, w' \rightarrow y, w'' \rightarrow 1 - y\} \\
\alpha_3 &= \{u' \rightarrow 0, v' \rightarrow 0, w' \rightarrow y, w'' \rightarrow 1 - y\}
\end{align*}
\]

The associated observations are:

\[
o_{\varphi_1} = o_{\alpha_1} = o_{\varphi_2} = o_{\alpha_2} = (\emptyset \rightarrow 0, \{a\} \rightarrow 1), o_{\varphi_3} = o_{\alpha_3} = (\emptyset \rightarrow 1, \{a\} \rightarrow 0).\]

The functions $\varphi_2, \varphi_3, \alpha_2$ and $\alpha_3$ together with their outputs are easily determined based on the operations of the corresponding Moore coalesage (as depicted in Fig. 9).

The connection between the behaviour, i.e., ready function of $p'$ (respectively, $u'$) and $\varphi_i$ (respectively, $\alpha_i$), for $i \in \{1, 2, 3\}$, is straightforward. Each of the functions $\varphi_1, \varphi_2$ and $\varphi_3$ captures the behaviour of the system starting from $p'$, after executing the traces $\varepsilon, a$ and $aa$, respectively. Note that, for example, the values of the ready function for trace $\varepsilon$ and ready sets $\emptyset$ and $\{a\}$, respectively, are in one to one correspondence with the assignments in $o_{\varphi_1}$. Similarly for the case of $u'$.

By following the same approach, the coalgebraic machinery provides an “yes” answer w.r.t. (maximal) failure equivalence of $p'$ and $u'$ as well. This is also in agreement with
the results in (Jou & Smolka 1990) stating that ready and (maximal) failure equivalence for GPS’s have the same distinguishing power.

The equivalence between the coalgebraic and the original definitions of the decorated trace semantics \( I \in \{ R_p, F_p, MF_p \} \) in (Jou & Smolka 1990) consists in showing that, given a GPS \((X, \delta), x \in X, w \in A^* \) and \( S \subseteq A \), it holds that \( \eta(x)(w)(S) = I(x)(w, S) \).

**Theorem 4.1.** Let \((X, \delta: X \rightarrow (D_\omega(X))^A)\) be a GPS and \((D_\omega(X), \langle o, t \rangle)\) be its associated determinization as in Fig. 9. Then, for all \( x \in X, w \in A^* \) and \( S \subseteq A \), it holds
\[
[\eta(x)](w)(S) = I(x)(w, S).
\]

**Proof.** The proof is similar for all \( I \) in \( \{ R_p, F_p, MF_p \} \), by induction on \( w \in A^* \).

---

**Base case – \( w = \varepsilon \):** \( [\eta(x)](\varepsilon)(S) = o = I(x)(\varepsilon, S) \).

---

**Induction step.** Here, we will use the fact that the map into the final coalgebra is also an algebra map and the equality
\[
I(x)(aw, S) = \sum_{y \in Y} \mu_a(x, y) \times I(x)(w)(S) \quad (\mu_a(x, x') = \delta(x)(a)(x'))
\]

4.2. (Maximal) trace semantics

In this section we provide the coalgebraic modelling of (maximal) trace semantics for GPS’s. The approach resembles the one in the previous section: we first recall the aforementioned semantics as introduced in (Jou & Smolka 1990), and then show how to instantiate the ingredients of Fig. 9 in order to capture the corresponding behaviours in terms of (final) Moore coalgebras. As a last step, we prove the equivalence between the coalgebraic modellings and the original definitions in (Jou & Smolka 1990).

**Definition 4.4 ((Maximal) trace equivalence (Jou & Smolka 1990)).**

The trace function \( T_p: X \rightarrow (A^* \rightarrow [0, 1]) \) is given by
\[
T_p(x)(w) = \sum_{y \in X} \mu_w(x, y).
\]

The maximal trace function \( MT_p: X \rightarrow [0, 1]^{A^*} \) is given by \( MT_p(x)(w) = \mu_w(x, 0) \).
We say that \( x, x' \in X \) are trace (resp. maximal) equivalent whenever \( T_p(x) = T_p(x') \) (resp. \( MT_p(x) = MT_p(x') \)).

From the definition above, it can be easily seen at an intuitive level that trace equivalence identifies processes that can execute with the same probability the same sets of traces \( w \in A^* \). Moreover, maximal trace equivalence takes into consideration the probability of not triggering any action after the performance of such \( w \)'s.

Therefore, we choose the set of observations \( B_I \) (where \( I = T_p \) for trace and \( I = MT_p \) for maximal trace semantics) to denote probabilities (of processes to execute \( w \in A^* \), or stagnate after triggering such \( w \)'s) ranging over \([0, 1]\).

We define the “decorating” functions, for \( I \in \{ T_p, MT_p \} \), \( \sigma_I : X \to [0, 1] \) by
\[
\sigma_{T_p}(x) = 1 \quad \sigma_{MT_p}(x) = \mu_0(x, 0)
\]
The (Moore) output function \( o \) is given by, for all \( \varphi \in \mathcal{D}_\omega(X) \),
\[
o(\varphi) = \sum_{x \in \text{supp}(\varphi)} \varphi(x) \times \sigma_I(x).
\]

We can now show the equivalence between the coalgebraic and the original definition of (maximal) trace semantics.

**Theorem 4.2.** Let \( (X, \delta : X \to (\mathcal{D}_\omega(X))^A) \) be a GPS and \( (\mathcal{D}_\omega(X), \langle o, t \rangle) \) be its associated determinization as in Fig. 9. Then, for all \( x \in X \) and \( w \in A^* \):
\[
[\eta(x)](w) = I(x)(w).
\]

**Proof.** By induction on \( w \in A^* \), similar to Theorem 4.1. □

Consider, for instance, the systems \( p' \) and \( u' \) in Example 4.1. They are trace equivalent as they both can execute traces \( \varepsilon, a \) and \( aa \) with total probability 1. Consequently, they are maximal trace equivalent as well: for sequences \( \varepsilon \) and \( a \), their associated maximal trace functions compute value 0, whereas for \( aa \) the latter return value 1.

The same answer w.r.t. (maximal) trace equivalence of \( p' \) and \( u' \) is obtained by reasoning on bisimilarity of their associated determinizations derived according to the powerset construction. It is easy to check that in the current setting, the Moore automata corresponding to \( \varphi_1 \) and \( \alpha_1 \) in Example 4.1 output
— in the case of trace: \( o_{\varphi_i} = o_{\alpha_i} = 1 \), for all \( i \in \{1, 2, 3\} \);
— in the case of maximal trace: \( o_{\varphi_i} = o_{\alpha_i} = 0 \), for \( i \in \{1, 2\} \) and \( o_{\varphi_3} = o_{\alpha_3} = 1 \).

Therefore \( \varphi_1 \) and \( \alpha_1 \) are bisimilar. Hence, \( p' \) and \( u' \) are (maximal) trace equivalent.

**5. In a nutshell: decorated trace equivalences for LTS’s and GPS’s**

Next we provide a more compact overview on the coalgebraic machineries introduced in Section 3 and Section 4. This also in order to emphasize on the generality and uniformity of our coalgebraic framework.

Recall that for each of the decorated trace semantics we first instantiate the constituents of Fig. 2 (summarizing the generalized powerset construction). Moreover, for
the case of LTS’s, the original definitions of the semantics under consideration are provided with equivalent representations in terms of functions $\varphi_T$, paving the way to their interpretation in terms of final Moore coaggebras.

All these are summarized in Fig. 10, for an arbitrary LTS $(X, \delta: X \to (\mathcal{P}_\omega X)^A)$ and an arbitrary GPS $(X, \delta: X \to (\mathcal{D}_\omega X)^A)$.

Once the ingredients of Fig. 2 and, for LTS’s, functions $\varphi_T$ are defined, we formalize the equivalence between the coalgebraic modelling of $\mathcal{I}$-semantics and its original definition.

For the case of LTS’s, for $\mathcal{I}$ ranging over $\mathcal{T}, \mathcal{C}_T, \mathcal{F}, \mathcal{R}, \mathcal{P}_F, \mathcal{R}_T$ and $\mathcal{F}_T$, we show that the following result holds:

**Theorem 5.1.** Let $(X, \delta: X \to (\mathcal{P}_\omega X)^A)$ be an LTS. For all $x \in X$, $[[x]] = \varphi_T \cong \mathcal{I}(x)$.

Orthogonally, for the case of GPS’s, for $\mathcal{I}$ ranging over $\mathcal{R}_p, \mathcal{F}_p, \mathcal{M}_F, \mathcal{T}_p$ and $\mathcal{M}_T \mathcal{T}_p$, we prove the following:

**Theorem 5.2.** Let $(X, \delta: X \to (\mathcal{D}_\omega X)^A)$ be a GPS. For all $x \in X$, $[\eta(x)] = \mathcal{I}(x)$.

For each of the semantics under consideration, the proofs of Theorem 5.1 and Theorem 5.2, follow by induction on words over the corresponding action alphabet. For more details see the proof of Theorem 3.1 in Section 3.1 (for LTS’s) and Theorem 4.1 in Section 4.1 (for GPS’s), respectively.

**Remark 5.1.** It is worth observing that by instantiating $T$ with the identity functor, $\mathcal{I}$ with $\mathcal{P}_\omega(-)^A$ and, respectively, $\mathcal{D}_\omega(-)^A$ in (3) one gets the coalgebraic modelling of the standard notion of bisimilarity for LTS’s and, respectively, GPS’s.

Concrete examples on how to use the coalgebraic frameworks are provided for each of the decorated trace semantics. We show how to derive determinizations of LTS’s and GPS’s in terms of Moore automata, which eventually are used to reason on the corresponding equivalences in terms of Moore bisimulations.

6. Canonical representatives

Given a decorated system $(X, (\tilde{\tau}, \delta))$, we showed in the previous sections how to construct a determinization $(T(X), (o, t))$, with $T = \mathcal{P}_\omega$ for the case of LTS’s, and $T = \mathcal{D}_\omega$ for GPS’s, respectively. The map $[[\cdot]]: TX \to B^A_T$ provides us with a canonical representative of the behaviour of each state in $TX$. The image $(C, \delta')$ of $(TX, (o, t))$, via the map $[[\cdot]]$, can be viewed as the minimization w.r.t. the equivalence $\mathcal{I}$.

Recall that the states of the final coalgebra $(B^A_T, (\epsilon, (-)_a))$ are functions $\varphi: A^* \to B_T$ and that their decorations and transitions are given by the functions $\epsilon: B^A_T \to B_T$ and $(-)_a: B^A_T \to (B^A_T)^A$, defined in Section 2. The states of the canonical representative $(C, \delta')$ are also functions $\varphi: A^* \to B_T$, i.e., $C \subseteq B^A_T$. Moreover, the function $\delta': C \to B_T \times C^A$ is simply the restriction of $\langle \epsilon, (-)_a \rangle$ to $C$, that means $\delta'(\varphi) = \langle \varphi(\epsilon), (\varphi)_a \rangle$ for all $\varphi \in C$.

Finally, it is interesting to observe that for LTS $B^A_T$ carries a semilattice structure (inherited from $B_T$) and that $[[\cdot]]: \mathcal{P}_\omega X \to B^A_T$ is a semilattice homomorphism. From this observation, it is immediate to conclude that also $C$ is a semilattice, but it is not
necessarily freely generated, i.e., it is not necessarily a powerset. Similarly, for GPS $B^*_T$ carries a positive convex algebra structure (these are the $D_\omega$-algebras) and $\square : \mathcal{D}_\omega X \rightarrow B^*_T$ is a positive convex algebra homomorphism. Again, from this observation, we know that also $C$ is a positive convex algebra (not necessarily freely generated).

7. Bisimulation up-to

As previously stated in the beginning of this paper, when reasoning on behavioural equivalence it is preferable to use relations as small as possible, that are not necessarily bisimulations, but contained in a bisimulation relation. These relations are referred to as \textit{bisimulations up-to} (Sangiorgi & Rutten 2011).

In what follows we exploit the generalized powerset construction summarized in Fig. 2 and define bisimulation up-to context in the setting of decorated LTS’s determined in terms of Moore automata. This comes as an extension of the recent work in (Bonchi & Pous 2013). Similar observations hold also for GPS’s, but we do not exploit them here.

Let $L_{dec} = (X, (\delta, \alpha), id) \circ \delta : X \rightarrow B_T \times (\mathcal{P}_\omega X)^A$ be a decorated (possibly “preprocessed”) LTS and $(\mathcal{P}_\omega X, (o,t) : \mathcal{P}_\omega X \rightarrow B_T \times (\mathcal{P}_\omega X)^A)$ its associated Moore automaton, as in Fig. 2. A \textit{bisimulation up-to context} for $L_{dec}$ is a relation $R \subseteq (\mathcal{P}_\omega X) \times (\mathcal{P}_\omega X)$ such that:

$$X_1 R X_2 \Rightarrow \left\{ \begin{array}{ll} o(X_1) = o(X_2) \\ (\forall a \in A). t(X_1)(a) c(R) t(X_2)(a) \end{array} \right.$$  \hspace{1cm} (13)

where $c(R)$ is the smallest relation which is closed with respect to set union and which includes $R$, inductively defined by the following inference rules:

<table>
<thead>
<tr>
<th>$I$</th>
<th>$\mathcal{B}_I$</th>
<th>$\bar{\delta}_I : X \rightarrow \mathcal{B}_I$</th>
<th>$I$</th>
<th>$\mathcal{B}_I$</th>
<th>$\bar{\delta}_I : X \rightarrow \mathcal{B}_I$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\mathcal{R}$</td>
<td>$\mathcal{P}<em>\omega(\mathcal{P}</em>\omega A)$</td>
<td>$\bar{\sigma}_\mathcal{R}(x) = (I(\delta(x)))$</td>
<td>$\mathcal{F}$</td>
<td>$\mathcal{P}<em>\omega(\mathcal{P}</em>\omega A)$</td>
<td>$\bar{\sigma}_{\mathcal{F}\mathcal{T}}(x) = \text{Fail}(\delta(x))$</td>
</tr>
</tbody>
</table>

\[ \begin{array}{l}
\mathcal{T} | \mathcal{P}_\omega(\mathcal{P}_\omega A) | \bar{\sigma}_\mathcal{T}(x) = 1 \\
\mathcal{C} | \mathcal{P}(\mathcal{P}_\omega A) | \bar{\delta}_\mathcal{C}(x) = \left\{ \begin{array}{ll} 1 & \text{if } I = I(x) \\
0 & \text{otherwise} \end{array} \right.
\end{array} \]
Remark 7.1. Observe that by replacing \( c(R) \) with \( R \) in (13) one gets the definition of Moore bisimulation.

**Theorem 7.1.** Any bisimulation up-to context for decorated LTS’s is included in a bisimulation relation.

**Proof.** The proof consists in showing that for any bisimulation up-to context \( R, c(R) \) is a bisimulation relation (recall that \( R \subseteq c(R) \)). The result follows by structural induction, as shown below.

Let \( L_{dec} = (X, \delta^t : X \to B_T \times (\mathcal{P}_\omega X)^A) \) be a decorated LTS and \((\mathcal{P}_\omega X, (o, t) : \mathcal{P}_\omega X \to B_T \times (\mathcal{P}_\omega X)^A)\) be its associated Moore automaton, derived according to the powerset construction. Let \( R \) be a bisimulation up-to context for \( L_{dec} \).

In what follows we want to prove that \( c(R) \) is a bisimulation relation (that includes \( R \), by (14)).

We have to show that

\[
X c(R) Y \Rightarrow \begin{cases} o(X) = o(Y) \\
(\forall a \in A). t(X)(a) c(R) t(Y)(a) \end{cases}
\]

We proceed by structural induction.

1. Let \( X R Y \). Then (15) holds by definition.

2. Let \( X = X_1 \cup X_2 \) and \( Y = Y_1 \cup Y_2 \) such that \( X_1 c(R) Y_1 \) and \( X_2 c(R) Y_2 \). By induction, we have that \( o(X_1) = o(Y_1) \) and \( o(X_2) = o(Y_2) \). We now need to prove that \( o(X) = o(Y) \).

\[
o(X) = o(X_1 \cup X_2) = o(X_1) \cup o(X_2) \overset{IH}{=} o(Y_1) \cup o(Y_2) = o(Y_1 \cup Y_2) = o(Y)
\]

We also have, by induction, that, for all \( a \in A \)

\[
t(X_1)(a) c(R) t(Y_1)(a) \quad \text{and} \quad t(X_2)(a) c(R) t(Y_2)(a)
\]

Hence, for all \( a \in A \), we can easily prove that \( t(X)(a) c(R) t(Y)(a) \):

\[
t(X)(a) = t(X_1 \cup X_2)(a) = t(X_1)(a) \cup t(X_2)(a) \quad \text{(IH)}
\]
\[
\quad c(R) \quad t(Y_1)(a) \cup t(Y_2)(a)
\]
\[
= t(Y_1 \cup Y_2)(a) = t(Y)(a)
\]

Hence, \( c(R) \supseteq R \) is a bisimulation relation, as (15) holds for all \((X, Y) \in c(R)\).

\[\square\]

**Remark 7.2.** Based on (1), (2) and Theorem 7.1, verifying behavioural equivalence of two states \( x_1, x_2 \) in a decorated LTS consists in identifying a bisimulation up-to context \( R^c \) relating \( \{x_1\} \) and \( \{x_2\} \):

\[
\|\{x_1\}\| = \|\{x_2\}\| \iff \{x_1\} R^c \{x_2\}.
\]

(16)

Also note that Theorem 7.1 is not a very different, but useful generalization of Theorem 2 in (Bonchi & Pous 2013) to the context of decorated LTS’s.
Example 7.1. We provide an example of applying the generalized powerset construction and bisimulation up-to context for reasoning on decorated trace equivalence of LTS’s.

Consider the following systems, where \(n\) is an arbitrary natural number:

It is easy to see that \(x\) and \(y\) are bisimilar: intuitively, all the states of the automata depicted above can trigger actions \(a\) and \(b\) as a first step and, moreover, all their subsequent transitions lead to states with the same behaviour. Therefore \(x\) and \(y\) are also \(I\)-equivalent for \(I\) ranging over \(\mathcal{T}, \mathcal{C}t, \mathcal{F}, \mathcal{R}, \mathcal{P}F, \mathcal{R}T\) and \(\mathcal{F}T\), according to the lattice of semantic equivalences in Fig. 1.

The coalgebraic machinery provides an “yes” answer w.r.t. \(I\)-equivalence of the two LTS’s as well. After determinization, \(\{x\}\) can reach all states of shape: \(\{x\} \cup \pi_i, \{x\} \cup \pi_j, \{x\} \cup \overline{\pi}_i \cup \overline{\pi}_j\), for \(i \in \{1, \ldots, n\}\) and \(\{x\} \cup \overline{\pi}_j \cup \{v_1\}, \{x\} \cup \overline{\pi}_j \cup \{u_1\}\), respectively, for \(j \in \{2, \ldots, n\}\). (We write, for example, \(\pi_i\) in order to represent the set \(\{u_1, u_2, \ldots, u_i\}\).)

Consequently, the generalized powerset construction associates to \(x\) a Moore automaton consisting of \(5n - 1\) states, whereas the determinization of \(y\) has only one state. Hence, the (Moore) bisimulation relation \(R\) including \(\{x, y\}\) consists of \(5n - 1\) pairs as follows:

\[
R = \{\{x, y\}\} \cup \{\{x\} \cup \pi_i \cup \{v_1\}, \{x\} \cup \pi_j \cup \{u_1\}, \{y\}\} | i \in \{2, \ldots, n\}\} \cup
\{\{x\} \cup \pi_i \cup \{y\}\}, \{x\} \cup \pi_j \cup \{y\}\}, \{x\} \cup \pi_i \cup \{y\}\} | i \in \{1, \ldots, n\}\}. \tag{17}
\]

For a better intuition, we illustrate below the determinizations starting from \(x\) and \(y\), for the case \(n = 3\):

It is easy to see that the bisimulation relating \(\{x\}\) and \(\{y\}\) consists of all pairs \((X, \{y\})\), with \(X\) ranging over the state space of the Moore automaton derived according to the generalized powerset construction, starting with \(\{x\}\).

Observe that all the pairs in \(R\) in (17) can be “generated” from \((\{x\}, \{y\}\), \((\{x\} \cup \pi_i, \{y\}\) and \((\{x\} \cup \pi_j, \{y\}\) by iteratively applying the rules in (14). Therefore, for an
arbitrary natural number $n$, the bisimulation up-to context stating the equivalence of $x$ and $y$ is:

$R^c = \{ (\{x\}, \{y\}) \} \cup \{ (\{x\} \cup u_i, \{y\}), (\{x\} \cup v_i, \{y\}) \mid i \in \{1, \ldots, n\} \}$

and consists of only $2n + 1$ pairs.

8. Conclusions and future work

In this paper, we have proved that the coalgebraic characterizations of decorated trace semantics for labelled transition systems and generative probabilistic systems, respectively, are equivalent with the corresponding standard definitions in (van Glabbeek 2001) and (Jou & Smolka 1990). More precisely, we have shown that for a state $x$, the coalgebraic canonical representative $\hat{J}(\{x\})$, given by determinization and finality, coincides with the classical semantics $I(x)$, for $I$ ranging over $T, CT, R, PF, RT$ and $FT$, representing the traces, complete traces, ready pairs, failure pairs, possible futures, ready traces and respectively failure traces of $x$ in a labelled transition system. Similar equivalences have been proven for $I$ ranging over $R_p, F_p, MF_p, T_p$ and $MT_p$ representing the ready, failure, maximal failure, trace and maximal trace functions for the case of probabilistic systems.

In addition, we have illustrated how to reason about decorated trace equivalence using coinduction, by constructing suitable bisimulations up-to context. This is a very efficient sound and complete proof technique, and represents an important step towards automated reasoning, as it opens the way for the use of, for instance, coinductive theorem provers such as CIRC (Rosu & Lucanu 2009). Last, but not least, we showed that the spectrum of decorated trace semantics can be recovered from the coalgebraic modelling.

Bisimulation up-to is a technique that has recently received renewed attention (Bonchi & Pous 2013, Rot, Bonsangue & Rutten 2013). The coalgebraic treatment thereof was originally studied by Lenisa (Lenisa 1999, Cancila et al. 2003) and further explored by Bartels (Bartels 2004).

A coalgebraic characterization of the spectrum, not based on the powerset construction, was attempted in (Monteiro 2008). The approach in (Monteiro 2008) is based on an abstract notion of “behaviour object” that has similar properties with final objects. It is not clear, however, how this approach could be modularly extended so to treat probabilistic decorated traces.

A similar idea of system determinization was also applied in (Cleaveland & Hennessy 1993), in a non-coalgebraic setting, for the case of testing semantics where must testing coincides with failure semantics in the absence of divergence. The approach in (Cleaveland & Hennessy 1993) is very similar to ours but it is restricted only to the case of testing semantics. Our use of coalgebraic techniques allows us to treat more decorated traces and also decorated probabilistic traces in essentially the same manner. Still in the context of must testing, a coalgebraic outlook is presented in (Boreale & Gadducci 2006) which introduces a fully abstract semantics for CSP. The main difference with our work consists in the fact that (Boreale & Gadducci 2006) build a coalgebra from the syntactic terms of CSP, while here we build a coalgebra starting from LTS’s via the generalized powerset.
construction (Silva et al. 2010). Moreover, they only consider must testing and leave
as future work capturing other decorated traces. In another paper (Bonchi, Caltais,
Pous & Silva 2013), we have shown that must testing can also be captured using the
generalized powerset construction. An important point is that our approach puts in
evidence the underlying semilattice structure which is needed for defining bisimulations
up-to whereas this is not at all considered in their paper. An interesting direction for
future work would be to explore combinations of both approaches: on the one hand, apply
up-to techniques to the their work; on the other hand, consider in our setting processes
specified by a certain syntax and generate the (determinized) LTS directly from
the expression specifying the process’ behavior. This would yield a coinductive approach to
denotational (linear-time) semantics of different kinds of processes calculi.

There are several other possible directions for future work. One option is to investi-
gate whether we can derive efficient algorithms implementing the proof techniques for
reasoning on decorated trace equivalences of labelled transition systems and generative
probabilistic systems, in an uniform fashion.

Orthogonally, it would be worth investigating whether there exists a coalgebraic rep-
resentation of system equivalences characterized by testing scenarios, or temporal logies,
along the lines in (van Glabbeek 2001).

Moreover, we aim at providing coalgebraic modellings for the remaining semantics
of the spectrum in (van Glabbeek 2001), and come up with a new representation of
possible-futures semantics. The latter is motivated by the current drawback of storing
for each state of the LTS’s the corresponding set of traces. In this context it might be
more appropriate considering the definition of possible-futures semantics given in terms
of nested bisimulations (Hennessy & Milner 1985), rather than the set-theoretic one
in (van Glabbeek 2001).
