Isocyanides can be polymerized to poly(iminomethylene) with NiCl$_2$ as a catalyst.

\[
n \text{R-N=C} \quad \overset{\text{Ni}^{II}}{\longrightarrow} \quad [\text{R-N=C}]_n
\]

The polymers have a rigid, helical structure with 4 repeating units per turn and a helical periodicity of 0.4 nm. The side chains of the polymers are arranged in 4 stacks parallel to the axis of the helix.

We have prepared a poly(iminomethylene) which contains coronand side chains by polymerizing 4-[(1-isocyanoethyl)benzo-18-crown-6 with nickel chloride. The coronands in the polymer form 4 molecular channels (Fig. 1), which strongly bind alkali and ammonium cations. The polymer provides a model for the study of ion transport through molecular channels in biological membranes.
