Reconsidering EU Compliance: Implementation performance in the field of environmental policy

Elena Bondarouk* and Ellen Mastenbroek
Radboud University, Institute for Management Research, the Netherlands

ABSTRACT
European Union (EU) environmental policy can only work in practice when it is implemented by and within the member states. Yet, despite its importance, we still lack a solid and cumulative understanding of the practical implementation of EU environmental policies, mainly because of the dominance of case-specific empirical insights and the dichotomous conceptualization of compliant implementation. This paper proposes a conceptual framework for analysing implementation performance, which is built around three dimensions: substance, scope and effort. The framework’s relevance and analytical quality are substantiated by a systematic review of empirical studies on practical implementation of 18 EU environmental directives. We find evidence of three types of knowledge deficits: there is neglect of the ‘scope’ and ‘effort’ dimensions of implementation; disproportionate attention to the Water Framework Directive, and the Northern and Western European member states. The proposed conceptual framework aims to inform future research on EU environmental implementation. © 2017 The Authors. Keywords: environmental policy; EU implementation; policy implementation; practical implementation; systematic review

Introduction

A KEY ISSUE IN ENVIRONMENTAL GOVERNANCE LIES IN ENSURING THAT AMBITIOUS POLICIES IN BOOKS ARE TRANSLATED INTO POLICIES IN action (Leventon and Antypas, 2012). This is no different for the European Union (EU), which is an active producer of environmental policies. The EU’s central environmental goals of greening the EU economy, protecting nature and safeguarding health and quality of life across the EU (Knill and Lenschow, 2000) are clearly undermined if EU policies are not complied with by the member states.

Consequently, a number of scholars of EU environmental governance have studied compliance with EU environmental policy, i.e. the national implementation of EU environmental policy (e.g. Bennett, 1993; Knill and Lenschow, 1998, 2000; Börzel, 2000; Börzel and Risse, 2000; Haverland, 2003; Bugdahn, 2005; Laffan and O’Mahony, 2008; Jans et al., 2009; Liefferink et al., 2011; Morris, 2011). This area of research has closely examined to what extent and how the EU’s member states have implemented the policy requirements laid down in various directives.

However, the literature on EU environmental policies has not produced a complete picture of the state of EU environmental implementation (Tosun, 2012). The reasons for this lack of overall insight are 2-fold. First, most existing studies are highly case-specific, deriving their operationalization of implementation conformity from the provisions of particular directives (Treib, 2014). This approach leads to the drawing of idiosyncratic conclusions, which do not reach a broader audience and hinder the accumulation of knowledge and the drawing of general conclusions (Töller, 2010; Tosun, 2012; Engeli and Allison, 2014; Treib, 2014; Schaffrin et al., 2015: 257).

Second, environmental implementation studies often evaluate implementation in dichotomous fashion – compliant or non-compliant implementation (e.g. Börzel, 2000; Bauer et al., 2007; Morris, 2011; see Treib, 2014 for more examples). This conceptualization of responses to EU policies is of restricted use in the field of EU environmental policy, given the growing use of procedural provisions and open norms (Scott, 2000; Börzel, 2003; Knill and Lenschow, 2004; Hartlapp and Falkner, 2009; Liefferink et al., 2011). The mere fact that a member state or local implementer lives up to a procedural obligation does not have any bearing on the extent to which the implementer really makes ‘EU policy work’ (Haverland and Romeijn, 2007). Accordingly, variation in implementation practices is not systematically assessed.

As a result, we are still in the dark about the extent to which and ways in which member states take EU environmental policy seriously (see Voermans, 2015). Answering this question requires a fully fledged conceptualization of the various aspects of implementation practices in response to EU legislation (Lange, 1999; Winter, 2006, 2012; Hupe, 2014; Thomann, 2015). To this end, the first goal of this paper is to develop and test a general ‘systematized concept’ (Adcock and Collier, 2001: 532) of implementation performance (Hill and Hupe, 2003: 475; Winter, 2006: 159; Hupe, 2011: 66) that goes beyond the details of specific directives, and captures variation in implementation.

This article uses a two-step deductive approach to construct the conceptualization. The first step is to derive aspects of implementation performance from the literatures on national policy implementation, analysis, design, evaluation and change. The second step is to compare the conceptual framework thus obtained with the insights from the literature on the practical implementation of EU environmental policies. We conduct a systematic literature review of case studies on practical implementation in the field of environmental policy published in the years 2010–2014, covering 18 different environmental directives. We check whether the framework is complete, and whether the categories are mutually exclusive. This second step also facilitates a second goal of this article: the isolation of knowledge gaps in the current research on practical implementation of environmental policies.

Finally, this study conveys lessons for the broader field of EU compliance (Treib, 2014). While the literature has repeatedly called for more research on the practical implementation of EU directives (e.g. Mastenbroek, 2005; Versluis, 2007; Treib, 2014), it has found itself in need of a useful concept for doing so systematically (Tosun, 2012; Treib, 2014). By developing and corroborating such a concept, this paper may step up compliance research in other policy sectors. We aim to pave the way for more systematic assessment of EU implementation performance in the field of environmental policy, thus facilitating knowledge accumulation (Tosun, 2012; Saetren, 2014; Sager et al., 2014; Thomann, 2015). Ultimately, the paper is expected to allow for fuller diagnosis and understanding of the implementation deficit that has been claimed to haunt the EU (Hupe, 2014: 170; Treib, 2014; Voermans, 2015: 365).

Setting the Scene: Defining Implementation Performance

Before systematically conceptualizing implementation performance, we need to define the concept’s core components: implementation and performance. Starting with the former, implementation refers to the stage between the transposition of EU directives and the enforcement of these directives by European or national actors. To differentiate it from transposition or legal transposition, this stage is also called practical implementation (Mastenbroek, 2005; Treib, 2014).

We argue that practical implementation consists of two distinct substages, the first of which we refer to as final policy formation on the ground. Hupe and Hill (2016: 106–107) argue that even at the stage of practical implementation there is a lot of decision making yet to be done. Any attempt to implement a policy always brings
Implementation Performance in the Field of Environmental Policy

new issues on the agenda and thus implementation and decision-making overlap (Lindblom and Woodhouse, 1993: 11; Hupe and Hill, 2016: 106). Even though generally overlooked in the EU implementation literature, this stage should be regarded as an important step in practical implementation, as it involves the local authority's efforts to operationalize national policy for practical purposes (Hill and Hupe, 2003: 479; Spicker, 2006: 44; Winter, 2006: 159; Versluis, 2007; Leventon and Antypas, 2012: 256; Steunenberg and Dimitrova, 2014: 7). During this substage, complex national policy – or transposed EU legislation, for that matter – is broken down into a series of tangible implementation tasks (Spicker, 2006: 43; Winter, 2006: 159). Furthermore, the responsible authority is assigned, a timescale within which the task is to be completed is established, and evaluation parameters are set (Spicker, 2006: 43; Winter, 2006: 159). If policy formation is completed, policy delivery (Versluis, 2007; Winter, 2012; Treib, 2014) commences. This second implementation stage is characterized by the actual putting in practice of the policy instruments. In environmental policy, typical examples are the enactment of physical measures or the provision of permits.

Having defined implementation, we move on to the definition of performance. The literature on policy analysis and implementation distinguishes two interpretations of performance. One focuses on policy outputs, e.g. the actions taken in response to law (Vedung, 1997; Hill and Hupe, 2003: 475; Winter, 2006: 159; Howlett et al., 2009: 183; Hupe, 2011: 66). The second interpretation focuses on policy outcomes, impacts or effects, i.e. the question of whether a policy indeed resolved the problem it set out to solve (Barrett and Fudge, 1981; Mastop and Faludi, 1997; Vedung, 1997; Berke et al., 2006; Winter, 2006: 159; Tosun, 2012: 440).

This study understands performance in the first way, i.e. in terms of outputs. It does so for a methodological reason, as an evaluation of EU policy impact is extremely challenging, because an isolation of the EU effect is practically impossible (Haverland, 2006; Tosun, 2012; Bauer and Knill, 2014). Any assessment of policy outputs presupposes a firm understanding of policy instruments: the techniques by which authorities attempt to change or maintain the policy status quo (Howlett et al., 2009; May, 2003: 225; Schaffrin et al., 2015). Being the building blocks of any policy (May, 2003: 225), policy instruments are the core of any policy output (Bauer and Knill, 2014; Schaffrin et al., 2015: 260).

We propose to compare implementation performance both in a vertical and in a horizontal manner. Where the EU standards are provided a vertical comparison is necessary, i.e. a comparison of implementation performance with the objectives set out in the superior EU law. Horizontal comparison, in turn, concerns the differences in implementation performance among implementers at the same administrative layer, e.g. municipalities, using the same policy instruments (Winter, 2006; Hupe, 2011).

This horizontal evaluation is especially relevant in cases when EU legislation leaves discretion to implementers or in case of procedural provisions. The discretion may result in great variance in implementation, which is still within the boundaries left by EU directives (Hartlapp and Falkner, 2009; Sager et al., 2014; Treib, 2014; Thomann, 2015). EU environmental law increasingly contains procedural provisions (Scott, 2000; Héritier, 2002; Börzel, 2003; Knill and Lenschow, 2004; Liefferink et al., 2011). These are designed to indirectly affect the desired policy outcome through the manipulation of policy processes (Huber and Shipan, 2002; Howlett et al., 2009). For example, implementers may have to develop an action plan to tackle an environmental problem. A mere vertical evaluation of implementation in this case would reduce a great variance in policy responses to a dichotomous notion of compliant versus non-compliant implementation. A horizontal evaluation in this case would allow for more benchmarking and thus also better insight into implementation practices.

These horizontal and vertical assessments of policy performance can be made on two dimensions: density and intensity (Knill et al., 2012; Bauer and Knill, 2014; Schaffrin et al., 2015). Policy density, firstly, refers merely to the number of policy instruments put in place to reach the policy objectives, i.e. the breadth and differentiation of legislative activity (Bauer and Knill, 2014: 33). Policy intensity, secondly, concerns the content of the policy instruments (Knill et al., 2012; Schaffrin et al., 2015), i.e. the breadth and differentiation of policy responses (Bauer and Knill, 2014: 33). To study to what extent local implementers make EU policy work, we specifically focus on intensity, as this sheds light on the policy commitment of local implementers (cf. Schaffrin et al., 2015: 261).

In summary, this article defines implementation performance as the intensity of policy outputs undertaken by implementers in response to EU policy instruments – relative to the directive’s objectives (vertical aspect) and to other implementers’ outputs (horizontal comparison). Given the importance of open norms and procedural requirements in EU environmental law (Knill and Lenschow, 1998, 2000; Scott, 2000; Newig and Fritsch, 2009;
The concept does not only have a vertical focus, i.e. aimed at comparing implementation with EU rules, but also a horizontal focus, i.e. aimed at comparing implementation practices between various implementing actors – either member states or units within these member states. The next section develops and specifies this concept by proposing three different analytical dimensions, together comprising 10 specific aspects.

Conceptual Framework

To capture the concept of policy performance in more depth and detail, this paper employs the approach of Adcock and Collier (2001). Accordingly, the concept of interest is broken down into different dimensions, to specify it in as detailed a fashion as possible. In doing so, we use and integrate the existing literature on national policy implementation, policy analysis, policy design, policy change and policy evaluation (e.g. Baldwin and Cave, 1999; Huber and Shipan, 2002; Spicker, 2006; Winter, 2006, 2012; Howlett et al., 2009; Hupe, 2011, 2014; Tosun, 2012; Bauer and Knill, 2014; Howlett and Cashore, 2014; Schaffrin et al., 2015).

Synthesizing this literature, three main dimensions of implementation performance emerge: substance, scope and effort. As illustrated in Figure 1, we propose to divide these three dimensions each into more refined aspects. The scores for these aspects are to be aggregated to form one score per dimension, which can be aggregated to one overall score. In the case of horizontal comparison, scoring is the result of comparison of the different implementers under study, e.g. regions, agencies or municipalities. In this case the scores on implementation performance are established relatively (Hupe, 2014: 173). When evaluating implementation performance, it is best to present both scores: the scores on different dimensions and the total score on implementation performance.

Dimension 1: Substance

Substance, the first dimension of implementation performance, relates to the essence of what central issue is being regulated by the policy instrument (cf. Steunenberg, 2007; König and Mäder, 2013; Zhelyazkova, 2013). The literature suggests two aspects of this dimension: definitional details and objectives of the policy instrument.

The first aspect of substance relates to the definitional details used during practical implementation (cf. Huber and Shipan, 2002: 51; Spicker, 2006: 43). The directive and its transposing measures may contain ambiguous elements that will be subjected to interpretation at practical implementation (Beijen, 2011: 152). When vertical evaluation of implementation performance is impossible, implementation performance will depend on how restrictively or comprehensively these elements are defined during practical implementation relative to other implementing peers (Howlett et al., 2009). The more specifically the definitional details are provided in the local statutes, the more.

Figure 1. Conceptual framework
specific and consistent implementation will be (cf. Baldwin and Cave, 1999: 43; Huber and Shipan, 2002: 50–51; Hupe, 2011: 69; Bauer and Knill, 2014: 33; Schaffrin et al., 2015: 264). There are three elements of definitional details that have to be defined in the practical implementation.

First, most directives contain a list of definitions in one of their first articles (Beijen, 2011). Still, these definitions may be open to interpretation, which may give rise to differences in implementation performance on the ground. The definitions of ‘waste’, ‘best available techniques’ and ‘discharge’, for instance, have given rise to much case law and literature (Beijen, 2011: 152). The absence of clear definitions becomes particularly relevant if the literal wording of a directive finds its way into national legislation, because local implementers will have to refine these concepts themselves to make them operational for practical implementation (Scott, 2000: 45–46; Spicker, 2006: 43; Beijen, 2011: 152). Second, a directive often contains a provision that an appropriate body should be appointed to implement the policy. The practical implementers are often tasked to define the responsibilities of persons or bodies who are engaged in the delivery of policy outputs (cf. Scott, 2000: 45–46; Huber and Shipan, 2002: 50–51; Schaffrin et al., 2015: 264). Lastly, definitional details relate to the exceptions when some tasks or actions should not be taken or are exempted from regulation (cf. Scott, 2000: 48). The more of such exemptions there are, the less comprehensive the practical implementation will be.

The second aspect of substance concerns the objectives of the policy instruments as adopted by the practical implementer. These objectives are ‘specific on-the-ground policy requirements’ (Knill et al., 2012; Leventon and Antypas, 2012: 256; Bauer and Knill, 2014: 33; Howlett and Cashore, 2014: 21). If objectives are set, the purpose of the policy is made transparent to the public and other political actors, and thus the implementers can be held responsible for the achievement of these goals (Schaffrin et al., 2015: 263). A directive contains two types of policy instruments, i.e. substantive and procedural, that have to be operationalized into practical objectives on the ground.

Substantive policy instruments include norms, standards or target values (Beijen, 2011: 154). Practical implementers may impose stricter or more lenient norms or standards in their own jurisdictions (Huber and Shipan, 2002: 50–55; Jans et al., 2009; Beijen, 2011: 154). For example, local governments may aim for higher air quality standards than the EU directive prescribes. Procedural policy instruments concern matters such as public participation, formulation of policy plans/reports, or the designation and protection of areas (Knill and Lenschow, 1998, 2000; Scott, 2000; Beijen, 2011; Newig and Koontz, 2014). For example, practical implementers are likely to differ in how they set the objectives for public participation. Policy performance in this respect may range from mere information provision to full implementation with voting procedures installed (cf. Huber and Shipan, 2002: 58; Howlett et al., 2009: 117–118). In the case of an obligation to formulate plans or reports, practical implementers will again set different objectives. These can vary in what types of measures are included in the plans, or what type of information is included in the reports (cf. Huber and Shipan, 2002: 58). As another example, practical implementers may set the criteria for designation and protection of areas in rather different ways (Beijen, 2011: 155).

**Dimension 2: Scope**

The second dimension of implementation performance concerns the scope of implementation (Beijen, 2011: 153; Bauer and Knill, 2014: 33; Thomann, 2015). This refers to the range of the policy: where, when and to whom does the policy task apply? If the scope is ambitious, it signals that an implementer takes the policy seriously (Schaffrin et al., 2015: 263). The literature has suggested three aspects of scope on which practical implementation may differ: territory, duration and addressees (Huber and Shipan, 2002: 49; Jans et al., 2009; Bauer and Knill, 2014: 33; Jenkins-Smith et al., 2014: 189). Depending on whether a directive or national legislation specifies these three aspects of scope, implementation performance should be evaluated either vertically or horizontally.

The first aspect of scope is the territory where the policy instrument applies (Jans et al., 2009; Bauer and Knill, 2014). Typically, the practical implementers may choose to make the policy instrument applicable to a whole region or only specific areas in a city. For example, local government may choose to target only a specific area in a city with extra air quality measures, while another will target the whole city. The second aspect of scope is temporal in nature, and concerns the duration of the policy task (Huber and Shipan, 2002; Jans et al., 2009; Bauer and Knill, 2014). For example, a specific policy plan may differ in terms of temporal span among the implementing authorities. The implementers may apply the environmental standards earlier or longer than determined in the national or EU policy instruments. The third aspect of scope captures how broad or specific the group of addressees targeted by the policy is.
(Jans et al., 2009; Bauer and Knill, 2014; Jenkins-Smith et al., 2014). Practical implementers may reduce or broaden the group targeted by the policy. For example, they may target a broader group of companies to perform an environmental impact assessment than the national or EU legislation prescribes. In the case of procedural policy instruments, this aspect of scope relates to, for instance, who is invited to the public consultation.

**Dimension 3: Effort**

The third and final dimension of implementation performance concerns the *effort* that implementers put into accomplishing a policy’s goals (Winter, 2006: 160; Howlett et al., 2009: 186; Bauer and Knill, 2014: 34). Effort refers to ‘the factors affecting the probability that substantial requirements are effectively achieved’ (Bauer and Knill, 2014: 34). The policy instruments that are characterized by higher intensity have more effort invested in them (Schaffrin et al., 2015: 262). Five aspects of the effort dimension emerge from the literature.

The first three aspects concern the resources that implementers allocate to implementation. The first aspect is the number of *staff*, i.e. organizational resources, designated to support the implementation of policy instruments (Hartlapp, 2009: 475; Tosun, 2012: 442; Bauer and Knill, 2014: 34; Schaffrin et al., 2015: 262). It relates to how many people in the organization are responsible for defining the policy tasks and carrying them out. The second aspect concerns the *types of expertise*, i.e. informational resources, involved to support policy implementation (Radaelli and De Francesco, 2007; Bauer and Knill, 2014: 34; Schaffrin et al., 2015: 262), which relates to the type of knowledge consulted during policy implementation. An example could be whether policy implementers have different backgrounds to facilitate the synergy of expertise and create a sound and feasible policy. The third aspect of effort is the percentage of an implementer’s *budget*, i.e. the financial resources, allocated to the implementation of policy goals (Bauer and Knill, 2014: 34; Schaffrin et al., 2015: 262–263). Because these resources are typically not specified in national or EU legislation, the assessment should be horizontal in nature.

The fourth aspect of effort concerns the *prioritization* of goals and measures within one policy (Winter, 2006: 160). Given their limited resources, implementers typically prioritize some goals or measures over others within the same policy. For example, a policy task might contain measures which the implementers are highly unlikely to implement in total. Therefore, one can analyse which measures or goals take precedence and receive most attention. The practical implementers are likely to vary in terms of what policy norms or measures are prioritized. Similarly to the first three aspects, prioritization is not specified by national or EU legislation, which necessitates horizontal comparison.

The final aspect of effort is *monitoring* (May and Winter, 1999; Howlett et al., 2009: 185; Beijen, 2011: 159; Tosun, 2012: 442; Bauer and Knill, 2014: 34; Schaffrin et al., 2015: 264). It describes how the practical implementer will assess the quality of the delivered task as well as the consequences of a failure to act, or how the practical implementers envision controlling for policy adherence (cf. Vedung, 1998: 31; Hartlapp, 2009: 475). Huber and Shipan (2002: 52) refer to it as the ‘quality assurance’ mechanism, which aims at ensuring policy adherence (see also May and Winter, 1999). The presence of such an enforcement mechanism signals to what extent practical implementers really make a policy work (Howlett et al., 2009; Schaffrin et al., 2015: 264). Depending on whether a directive or national legislation prescribes local monitoring, implementation performance on these aspects should be evaluated vertically or horizontally.

**Research Design**

Having conceptualized implementation performance, several questions present themselves. First, is the framework complete when compared to existing empirical studies of implementation? Second, are the theoretical aspects proposed mutually exclusive within a dimension (Schreier, 2012: 75)? Hence the collective exhaustiveness and mutual exclusiveness of the framework’s dimensions must be corroborated (Schreier, 2012: 75). And third, how complete is our understanding of implementation performance in the field of EU environmental policy?

To answer these questions, a deductive qualitative content analysis (Schreier, 2012) was conducted, comparing the conceptual framework with existing empirical studies of practical implementation of specific environmental
Implementation Performance in the Field of Environmental Policy

directives. This analysis reduces the data by classifying the specific and concrete information from the earlier studies under the aspects of our conceptual framework (Potter and Levine-Donnerstein, 1999; Schreier, 2012).

These existing studies, published in journals, served as data for our analysis. The studies were selected using a systematic literature review method to avoid any intentional or unintentional bias in the selection of the data (Petticrew and Roberts, 2006). Web of Science (Thomson), one of the largest scientific databases for the social and environmental sciences, was selected for the collection of data. The data were selected in five steps in July 2014.

First, as this research is interested in implementation and compliance with EU directives, a Boolean search was carried out using the keywords ‘(EU OR directive) AND (implement* OR compliance)’. Web of Science yielded 7989 documents with these keywords in either the title and/or the abstract of the documents. Second, the analysis was limited to academic articles, because these enjoy peer review which safeguards quality. The sample was restricted to articles written in English and dealing with environmental policy. This selection resulted in 940 articles. Third, the titles and the abstracts were closely read, to include only those articles that deal with the practical implementation of EU directives. Articles focusing on policy outcomes, cost–benefit analysis of policy implementation, technical calculations or anything else except implementation performance were excluded. This selection step yielded 187 articles. To validate this sample, we checked whether the articles on practical implementation of EU environmental directives identified in more general EU literature reviews (Angelova et al., 2012; Treib, 2014; Toshkov et al., n.d.) were also included in our sample of 187 articles. This was indeed the case. Fourth, aiming to grasp current knowledge, articles were selected if published in the previous 5 years, i.e. 2010–2014. This resulted in a database of 112 articles. As a final selection step, we applied the same inclusion and exclusion criteria as in step 3 of the selection process to the full texts of the articles. This led to the final identification of 70 articles2 to be subjected to the qualitative content analysis.

For this analysis we coded these 70 articles based on the conceptual framework. We used a standard coding procedure (Schreier, 2012). Following this procedure, a codebook was developed, which contained operational definitions of the previously defined 10 aspects of implementation performance. Analysis of the first two articles yielded typical examples for all aspects, which were added to the codebook. The deductive analysis of the articles was performed using NVivo 10 software.

To examine the framework’s quality, i.e. the collective exhaustiveness and mutual exclusiveness of the framework’s dimensions, the following three steps were taken. First, to corroborate the concept’s exhaustiveness, an additional code was created to keep track of any descriptions that would not fit the framework. Such instances were to be coded as ‘emerging themes’. Second, to examine the mutual exclusiveness of aspects of one dimension, we checked whether the coding units had overlapping aspect-codes assigned to them (Schreier, 2012). And third, the coding was subjected to consistency control, i.e. reliability, by two additional coders (Krippendorf, 2004: 215; Schreier, 2012: 169). A strong measure of reliability and thus also quality assurance of the coding scheme, i.e. the conceptual framework, is to examine whether others can interpret the data by coding it in the same manner, or at least agree on the interpretation of the data (Krippendorf, 2004: 215; Schreier, 2012: 169).

This intercoder reliability examination was established in two ways. The articles were divided into two roughly equal and mutually exclusive subsets. The first subset \(n = 36\) was divided between the two coders and subjected to independent coding of the result sections of the articles. The second subset \(n = 34\) was also divided between these two coders, but instead of independent coding the coding of the main coder was checked by these two coders. The coders were instructed to keep track of any data that would not fit the framework, and code these as ‘emerging themes’. These two different ways of performing intercoder reliability assessment are the most common ways of examining the reliability of coding (Schreier, 2012: 169).

To evaluate the completeness and coverage of our understanding of implementation performance in the field of EU environmental policy, the following three steps were taken. First, by coding 70 articles on the aspects of the conceptual framework we reflected on the state-of-the-art knowledge of implementation performance. Such analysis allowed us to see which aspects have received most empirical attention so far, and to identify any gaps in our understanding of environmental policy implementation. Second, we kept track of what directives were examined to see whether some directives have received more attention and whether there are systematic differences in how

2For this list, please see the online Appendix.

DOI: 10.1002/eet
Implementation performance was evaluated based on the directive at stake. And third, for the same reasons, we also kept track of what countries were studied in these articles.

### Analysis

As depicted in Table 1, the sample covers 18 EU environmental directives. In total, 32 articles (46%) focus on the Water Framework Directive (WFD). Seven articles cover multiple directives in their study. The EU Strategic Environmental Assessment Directive is examined by six articles, the Natura 2000 by five articles, and the Environmental Noise Directive and Habitats Directive by three articles each.

As can be seen in Table 2, the sample covers 19 different member states. Seventeen articles (24%) examined two or more countries. The top five most examined countries in the sample are UK, Germany, Ireland, Italy and the Netherlands.

Moving to the quality of the framework, the analysis revealed that the conceptual framework captures implementation performance, as defined by the existing directive-specific studies, rather well. In the first place, none of the coders assigned the ‘emerging themes’ code, implying that all aspects of implementation performance covered by the existing studies could be subsumed under one of the headings of our conceptual framework. Accordingly, it seems safe to conclude that this forms a complete representation of implementation performance.

Secondly, to assess the mutual exclusiveness of aspects within one dimension, we checked whether different framework aspect codes were assigned to the same coding unit. No such overlapping coding was found. Third, the two subsets of data displayed high intercoder reliability agreement: 75% agreement for the whole framework in the first subset (column A, Table 3), and 95% agreement in the second subset (column B). It thus seems safe to conclude that others interpret the same data in the same way, using this conceptual framework.

The next step in the analysis was to evaluate the state of knowledge on implementation performance in the field of EU environmental policy. Here, the analysis reveals that our knowledge is fragmented in three ways. First, we see variant coverage of the 10 aspects of implementation performance in existing studies. Whereas none of the articles covered all the proposed aspects, all reported at least one aspect of the conceptual framework. In total, 19% of articles used eight of the aspects to examine implementation performance, another 19% used seven aspects, followed by 16% elaborating on five aspects, 13% on six aspects, 11% on four aspects and 9% on nine aspects. More specifically, Table 3 presents the relative frequency scores of the conceptual framework aspects. Column C shows that the ‘objectives’ aspect received most attention, followed by ‘expertise’, ‘definitionals details’ and ‘monitoring’. The popularity of the ‘objectives’ aspect is not surprising: it is an intuitive first step in implementation research to

---

3This is not surprising as the first type of intercoder reliability test is a more critical reliability assessment (Schreier, 2012).
4As most articles paid attention to different aspects at the same time, the relative frequency scores do not add up to 100%.
examine which of the prescribed policy instruments have been put in place and applied when studying practical implementation. Much less attention, however, has been paid to the ‘scope’ and ‘effort’ dimensions of implementation performance. This is surprising, given their theoretical importance for implementation performance. Only a few articles paid attention to ‘staff’ and ‘prioritization’ aspects. In sum, our analysis reveals important knowledge gaps in implementation performance in EU environmental policy.

Second, as already mentioned, a large proportion of the sample (32 articles) focused on the WFD (Table 1). Columns D and E of Table 3 show that our knowledge on WFD implementation performance is much more extensive than that on other directives, especially when it comes to the ‘scope’ and ‘effort’ dimensions. Another large proportion of the sample (12 articles) focused on more than one directive, i.e. multiple directives and Natura 2000 directives. Column F shows that many of these articles covered various aspects of the conceptual framework. However, little attention has been paid to the ‘monitoring’, ‘territory’, ‘staff’ and ‘prioritization’ aspects of implementation performance.

Third, the analysis shows that our insights on implementation performance mostly stem from case studies on Western member states, which are expected to have a relatively smooth practical implementation (Falkner and

*Number of articles in the sample.
†World of law observance and world of domestic politics.
‡World of dead letters and world of transposition neglect.
Note: the percentages do not add up to 100% in columns C to H as a single article focuses on different aspects in the same study.
Treib, 2008). According to Falkner and Treib’s (2008) typology of the worlds of compliance, we divided the countries in the sample into two groups. Falkner and Treib (2008) argue that practical implementation of EU directives will run more smoothly in the countries of the ‘world of law observance’ and the ‘world of domestic politics’\(^5\) (column G, Table 3) than in countries of the ‘world of dead letters’ and the ‘world of transposition neglect’ (column H, Table 3). It seems that we know relatively less on the ‘scope’ dimension of the implementation performance in the countries where practical implementation was hypothesized to be more problematic (column H) than in the countries where implementation can be expected to be smoother (column G). The opposite seems to hold for the ‘effort’ dimension of implementation performance, where we know relatively more of this dimension of implementation performance in countries with hypothesized problematic implementation. This finding demonstrates the need to study implementation performance more systematically to draw better conclusions on how ‘problematic’ the implementation of EU directives actually is and how seriously the implementers take EU policies. As for now, due to the fragmented nature of our knowledge on the implementation performance important information might have been omitted from its evaluation.

**Conclusions**

This paper has proposed a three-dimensional conceptual framework for studying EU implementation performance that allows for systematic analysis of variation in practical implementation, while going beyond a conventional dichotomous understanding of compliance. The validity of the theoretically deduced conceptual framework was corroborated by an extensive qualitative content analysis of previous policy-specific empirical research on the implementation of EU environmental directives.

Even though environmental policy has been often claimed to be the most extensively researched policy field, the systematic literature analysis reported in this paper revealed that our knowledge of the practical implementation of EU environmental directives is fragmented in three ways. First, so far the various aspects of EU implementation performance have been examined neither equally nor systematically. While the ‘substance’ dimension has received most attention in the literature, much less attention has been paid to the ‘scope’ and ‘effort’ dimensions. Second, there is a need for the examination of practical implementation of directives other than the WFD, as other environmental directives have not been examined as frequently and as systematically as the WFD. When comparing the implementation of different directives, it is important to pay attention to ‘monitoring’, ‘territory’, ‘staff’ and ‘prioritization’ aspects, as these have received less attention up until now. And third, the analysis has revealed the need for more systematic research into countries where the practical implementation can be expected to be relatively problematic.

If the goal of research into EU environmental policy implementation, but also EU compliance, is to understand to what extent the member states really make EU policies work, there is a need for a more systematic approach to study implementation performance than has been practised up until now. If we continue to argue that there is a compliance deficit in the EU, we need to pinpoint exactly where, how and what is lacking in policy implementation. This conceptual framework can facilitate such research by offering a fully fledged conceptualization of implementation performance.
