Enhanced polarizations of top quarks produced at the Tevatron collider are almost unpolarized, while models beyond the standard model (BSM) predict nearly no polarization. This is the first measurement of top quark polarization at the Tevatron using lepton polarization in $t\bar{t}$ production. The observed distributions are consistent with standard model predictions of CP conservation. The $P_{\hat{n}}$ can be obtained from the asymmetry of the $\cos \theta$ distribution

$$A_{P,\hat{n}} = \frac{N(\cos \theta_{l,\hat{n}} > 0) - N(\cos \theta_{l,\hat{n}} < 0)}{N(\cos \theta_{l,\hat{n}} > 0) + N(\cos \theta_{l,\hat{n}} < 0)},$$

where $N(x)$ is the number of events passing the requirement $x$ and the polarization is then $P_{\hat{n}} = 2A_{P,\hat{n}}$. The quantization axes are defined in the $\hat{n}$ rest frame, while for $d$-type quarks, $-0.4$ for $b$-quarks, and $-0.3$ for neutrinos and $u$-type quarks [3], and $\theta_{l,\hat{n}}$ is the angle between the direction of the decay product $i$ and the quantization axis $\hat{n}$. The mean polarizations of the top and antitop quarks are expected to be identical because of CP conservation. The $P_{\hat{n}}$ can be obtained from the asymmetry of the $\cos \theta$ distribution

$$A_{P,\hat{n}} = \frac{N(\cos \theta_{l,\hat{n}} > 0) - N(\cos \theta_{l,\hat{n}} < 0)}{N(\cos \theta_{l,\hat{n}} > 0) + N(\cos \theta_{l,\hat{n}} < 0)},$$

where $N(x)$ is the number of events passing the requirement $x$ and the polarization is then $P_{\hat{n}} = 2A_{P,\hat{n}}$. The quantization axes are defined in the $\hat{n}$ rest frame, while for $d$-type quarks, $-0.4$ for $b$-quarks, and $-0.3$ for neutrinos and $u$-type quarks [3], and $\theta_{l,\hat{n}}$ is the angle between the direction of the decay product $i$ and the quantization axis $\hat{n}$. The mean polarizations of the top and antitop quarks are expected to be identical because of CP conservation.
the decay product directions are defined after successively boosting the particles to the $\bar{t}t$ rest frame and then to the parent top quark rest frame. We measure the polarization along three quantization axes: (i) the beam axis $\hat{n}_p$, given by the direction of the proton beam [2]; (ii) the helicity axis $\hat{n}_h$, given by the direction of the parent top or antitop quark; and (iii) the transverse axis $\hat{n}_T$, given as perpendicular to the production plane defined by the proton and parent top quark directions, i.e., $\hat{n}_p \times \hat{n}_h$ (or by $\hat{n}_p \times -\hat{n}_T$ for the antitop quark) [4,5].

The D0 Collaboration published a short study of the top quark polarization along the helicity axis in $p\bar{p}$ collisions as part of the measurement of angular asymmetries of leptons [6], but no measured value was presented. Recently, the D0 Collaboration measured the top quark polarization along the beam axis in $\bar{t}t$ final states with two leptons [7], finding it to be consistent with the SM. The ATLAS and CMS collaborations measured the top quark polarization along the helicity axis in $pp$ collisions, and the results are consistent with no polarization [8,9].

The longitudinal polarizations along the beam and helicity axes at the Tevatron collider are predicted by the SM to be ($-0.19 \pm 0.05$)% and ($-0.39 \pm 0.04$)% [12], respectively, while the transverse polarization is estimated to be $\approx 1.1$% [5]. Observation of a significant departure from the expected value would be evidence for BSM contributions to the top quark polarization [1].

We present a measurement of top quark polarization in $\ell^+ +$ jets final states of $\bar{t}t$ production using data collected with the D0 detector [13], corresponding to an integrated luminosity of 9.7 fb$^{-1}$ of $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV. The lepton is most sensitive to the polarization and is easily identified. We therefore examine the angular distribution of leptons. After selecting the events in the $\ell^+ +$ jets final state, we perform a kinematic fit to reconstruct the lepton angles relative to the various axes. The resulting distributions are fitted with mixtures of signal templates with $+1$ and $-1$ polarizations to extract the observed values. The down-type quark has an analyzing power close to unity, but its identification is difficult. It is therefore not used in the measurement. However, to gain statistical precision, we use reweighted Monte Carlo (MC) down-type quark distributions in forming signal event templates.

**II. EVENT SELECTION**

Each top quark of the $\bar{t}t$ pair decays into a $b$ quark and a $W$ boson with nearly 100% probability, leading to a $W^+W^-b\bar{b}$ final state. In $\ell^+ +$ jets events, one of the $W$ bosons decays leptonically and the other into quarks that evolve into jets. The trigger selects $\ell^+ +$ jets events with at least one lepton, electron ($e$) or a muon ($\mu$). The efficiency of the trigger is 95% or 80% for $\bar{t}t$ events containing reconstructed $e$ or $\mu$ candidates, respectively. This analysis requires the presence of one isolated $e$ [14] or $\mu$ [15] with transverse momentum $p_T > 20$ GeV and physics pseudorapidity $|\eta| < 1.1$ or $|\eta| < 2$, respectively. In addition, leptons are required to originate from within 1 cm of the primary $p\bar{p}$ interaction vertex (PV) in the coordinate along the beam axis. Accepted events must have a reconstructed PV within 60 cm of the center of the detector along the beam axis. Furthermore, we require an imbalance in transverse momentum $p_T > 20$ GeV, expected from the undetected neutrino. Jets are reconstructed using an iterative cone algorithm [17] with a cone parameter of $R = 0.5$. Jet energies are corrected to the particle level using calibrations from studies of exclusive $\gamma +$ jet, $Z +$ jet, and dijet events [18]. These calibrations account for differences in the detector response to jets originating from gluons; $b$ quarks; and $u$, $d$, $s$, or $c$ quarks. We require at least three jets with $p_T > 20$ GeV within $|\eta| < 2.5$ and $p_T > 40$ GeV for the jet of highest $p_T$. At least one jet per event is required to be identified as originating from a $b$ quark ($b$ tagged) through the use of a multivariate algorithm [19]. In $\mu +$ jets events, upper limits are required on the transverse mass of the reconstructed $W$ boson [20] of $M_T^W < 250$ GeV and $p_T < 250$ GeV to remove events with misreconstructed muon $p_T$. Additional selections are applied to reduce backgrounds in muon events and to suppress contributions from multijet production. A detailed description of these requirements can be found in Ref. [21]. In addition, we require the curvature of the track associated with the lepton to be well measured to reduce lepton charge misidentification.

**III. SIGNAL AND BACKGROUND SAMPLES**

We simulate $\bar{t}t$ events at the next-to-leading-order (NLO) in perturbative QCD with the MC@NLO event generator version 3.4 [22] and at the leading-order (LO) with ALPGEN event generator version 2.11 [23]. Parton showering, hadronization, and modeling of the underlying event are performed with HERWIG [24] for MC@NLO events and with PYTHIA 6.4 [25] for ALPGEN events. The detector response is simulated using GEANT3 [26]. To model the effects of multiple $p\bar{p}$ interactions, the MC events are overlaid with events from random $p\bar{p}$ collisions with the same luminosity distribution as the data. The main background to the $\bar{t}t$ signal is $W +$ jets events, where the $W$ boson is produced via the electroweak interaction together with additional partons from QCD radiation. The $W +$ jets final state can be split into four subsamples according to parton flavor, $Wb\bar{b}$ + jets, $Wc\bar{c}$ + jets, $Wc +$ jets, and $W +$ light jets, where light refers to gluons, $u$, $d$, or $s$ quarks. The $W +$ jets
background is modeled with ALPGEN and PYTHIA [23,25], as is the background from Z + jets events. Other background processes include WW, WZ, and ZZ diboson productions simulated using PYTHIA and single top quark electroweak production simulated using COMPHEP [27]. The multijet background, where a jet is misidentified as an isolated lepton, is estimated from the data using the matrix method [21,28]. We use six different BSM models [29] to study modified $t\bar{t}$ production: one $Z'$ boson model and five axigluon models with different axigluon masses and couplings (m200R, m200L, m200A, m2000R, and m2000A, where L, R, and A refer to left-handed, right-handed, and axial couplings and numbers are the particle masses in GeV). Some additional axigluon models such as m2000L are not simulated as they are excluded by other constraints the selection requirements and the maximum-likelihood fit solutions in each event; $\chi^2$ jet candidate from $t\rightarrow b\ell\nu$ decay, and $b_{had}$, the $b$ jet candidate from the $t\rightarrow bq'\nu$ decay; and $m_{jj}$, the invariant mass of the two jets corresponding to the $W\rightarrow q\bar{q}'$ decay.

The sample composition is determined from a simultaneous maximum-likelihood fit to the kinematic discriminant distributions. The $W + jets$ background is normalized separately for the heavy-flavor contribution ($Wb\bar{b}$ + jets and $Wc\bar{c}$ + jets) and for the light-parton contribution ($Wc +$ jets and $W +$ light jets). The sample composition after implementing the selections, and fitting the maximum likelihood to data, is broken down into individual channels by lepton flavor and number of jets and summarized in Table I. The obtained $t\bar{t}$ yield is close to the expectations.

The lepton angular distributions in $W + jets$ events must be well modeled since these events form the leading background, especially in the $\ell + 3$ jet sample. We therefore use a control sample of $\ell + 3$ jet events without $b$ tagged jets, as such events are dominated by $W +$ jets production with $>70\%$ contribution. This sample is not used for the polarization measurement. We reweight the $W + jets$ MC events so that the $\cos\theta_{\ell,\hat{b}}$ distributions agree with those for the control events in data with $t\bar{t}$ and other background components subtracted. We use the relative polarization asymmetry defined as $[N_j(\cos\theta_{\ell,\hat{b}}) - N_{-j}(\cos\theta_{\ell,\hat{b}})]/[N_j(\cos\theta_{\ell,\hat{b}}) + N_{-j}(\cos\theta_{\ell,\hat{b}})]$, where $j$ refers to bins of $\cos\theta_{\ell,\hat{b}}$ values between 0 and 1 and $-j$ refers to bins between -1 and 0. The distributions of simulated $W +$ jets events and subtracted data are shown in Fig. 1. The correction to MC obtained from the control sample is applied to the background templates used in our signal extraction. The corrections are $0.047 \pm 0.002$ for polarization along the beam axis, $0.011 \pm 0.001$ for the

### IV. ANALYSIS METHOD

A constrained kinematic $\chi^2$ fit is used to associate the observed leptons and jets with the individual top quarks using a likelihood term for each jet-to-quark assignment, as described in Ref. [31]. We assume the four jets with largest $p_T$ to originate from $t\bar{t}$ decay in events with more than four jets. The algorithm includes a technique that reconstructs events with a lepton and only three jets [32]. The addition of the three-jet sample almost doubles the signal sample as shown in Table I. In our analysis, all possible assignments of jets to final state quarks are considered and weighted by the $\chi^2$ probability of each kinematic fit and by the $b$ tagging probability.

To determine the sample composition, we construct a kinematic discriminant based on the approximate likelihood ratio of expectations for $t\bar{t}$ and $W + jets$ events [33]. The input variables are chosen to achieve good separation between $t\bar{t}$ and $W +$ jets events and required to be well modeled and not strongly correlated with one another or with the lepton polar angles used in the measurement. Sets of input variables are selected independently for the $\ell + 3$ jet and the $\ell + \geq 4$ jet events, each in three subchannels according to the number of $b$ tagged jets: 0, 1, $\geq 2$. The channels without $b$ tagged jets are used to determine the sample composition and background calibration, not to measure the polarization.

The input variables used for the $\ell + 3$ jet kinematic discriminant are $k_{min}^{t\bar{t}} = \min(p_{T,a}, p_{T,b}) \cdot \Delta R_{ab}$, where $\Delta R_{ab} = \sqrt{(\eta_a - \eta_b)^2 + (\phi_a - \phi_b)^2}$ is the angular distance between the two closest jets ($a$ and $b$), $\min(p_{T,a}, p_{T,b})$ represents the smaller transverse momentum of the two jets, and the $\phi$ are their azimuths in radians; aplanarity $A = 3/2\lambda_3$, where $\lambda_3$ is the smallest eigenvalue of the normalized momentum tensor; $H_T^j$, which is the scalar sum of the $p_T$ of the jets and lepton; $\Delta R$ between the leading jet and the next-to-leading jet; and $\Delta R$ between the lepton and the leading jet.

The input variables for the $\ell + \geq 4$ jet discriminant are $k_{min}^{t\bar{t}}$; aplanarity; $H_T^j$; centrality, $C = H_T/H$, where $H_T$ is the scalar sum of all jet $p_T$ values and $H$ is the scalar sum of all jet energies; the lowest $\chi^2$ among the different kinematic fit solutions in each event; $(p_{T,a}^{had} - p_{T,a}^{lep})/(p_{T,a}^{had} + p_{T,a}^{lep})$, the relative $p_T$ difference between $b_{lep}$, the $b$ jet candidate from the $t\rightarrow b\ell\nu$ decay, and $b_{had}$, the $b$ jet candidate from the $t\rightarrow bq'\nu$ decay; and $m_{jj}$, the invariant mass of the two jets corresponding to the $W\rightarrow q\bar{q}'$ decay.

the expected event yield. The signal templates arise from
$\Gamma_{W}$ and $\Gamma_{\text{C}}$.

We use the SM values

$$C = -0.368 \text{ (helicity axis)}$$

and in electroweak couplings in Ref. [2]. The spin
correlation factor is not known for the transverse axis,
and thus we set $C = 0$ and assign a systematic uncertainty
by varying the choice of this factor. The $P_{\hat{n},i}$ represents the
polarization state we model (here $P_{\hat{n},i} = \pm 1$) along the
chosen axis $\hat{n}$. In the SM, assuming $CP$ invariance, $P_{\hat{n},1} =$ $P_{\hat{n},2}$ and gives the relative sign factor $\rho$ a value of $+1$ for the
helicity axis and $-1$ for the beam and transverse axes [2].

A simultaneous fit is performed for the eight samples
defined according to lepton flavor ($e$ or $\mu$), lepton charge, and
number of jets (3 or $\geq 4$). The observed polarization is taken
as $P = f_+ - f_-$, where $f_\pm$ are the fraction of events with
$P = +1$ and $-1$ returned from the fit. The fitting procedure
and methodological approach are verified using pseudoe-
periments for five values of polarization and through a check
of consistency with predictions, using the BSM models with
nonzero generated longitudinal polarizations. The fitted polarizations
and the model inputs are in good agreement,
as shown in Fig. 2 for the polarizations along the beam axis,
thus verifying our template methodology. The distributions
in the cosine of the polar angle of leptons from $\bar{t}t$ decay for all
three axes are shown in Fig. 3.

A previous measurement of top quark polarization and the
forward-backward $t \bar{t}$ and $\bar{t}t$ asymmetry in dilepton final states
[7] noted a correlation between these two measurements.
This correlation is caused by acceptance and resolution
effects in the kinematic reconstruction of the events. We
determine the dependence of the observed polarization on
the forward-backward asymmetry at the parton level,
$A_{FB}$, using samples in which the $t$ and $\bar{t}$ rapidity distributions are
rewighted to accommodate the polarizations. We then use a
correction for the difference between the nominal MC@NLO

transverse axis, and a negligible amount for the helicity axis.
The uncertainties are propagated to the measurement
as a systematic uncertainty of the background modeling.

We observe the $W +$ jets events to have polarization,
calculated as in Eq. (2), of $+0.18$ along the beam axis,$-0.23$ along the helicity axis, and $-0.02$ along the trans-
verse axis. Other backgrounds give polarizations of $+0.05$
(beam axis), $-0.30$ (helicity axis), and $+0.01$ (trans-
verse axis).

To measure the polarization, a fit is performed to the
reconstructed $\cos \theta_{\ell,\hat{n}}$ distribution using $\bar{t}t$ templates of $+1$
and $-1$ polarizations and background templates normalized
to the expected event yield. The signal templates arise from
the $\bar{t}t$ MC sample generated with no polarization but
rewighted to follow the expected double differential
distribution [2],

$$\frac{1}{\Gamma} \frac{d\Gamma}{d \cos \theta_1 \cos \theta_2} = \frac{1}{4} \left( 1 + \kappa_1 P_{\hat{n},1} \cos \theta_1 + \rho \kappa_2 P_{\hat{n},2} \cos \theta_2 \
- \kappa_1 \kappa_2 C \cos \theta_1 \cos \theta_2 \right),$$

where indices 1 and 2 represent the $t$ and $\bar{t}$ quark decay
products (the leptons and down quarks, or their charge
conjugates), $\kappa$ is the spin-analyzing power, and $C$ is the $\bar{t}t$
spin correlation coefficient for a given quantization axis.
We use the SM values

$$C = 0.791 \text{ (beam axis)},$$

both calculated at NLO in QCD

interactions, and in electroweak couplings in Ref. [2].

A previous measurement of top quark polarization and the
forward-backward $t \bar{t}$ and $\bar{t}t$ asymmetry in dilepton final states
[7] noted a correlation between these two measurements.
This correlation is caused by acceptance and resolution
effects in the kinematic reconstruction of the events. We
determine the dependence of the observed polarization on
the forward-backward asymmetry at the parton level,
$A_{FB}$, using samples in which the $t$ and $\bar{t}$ rapidity distributions are
rewighted to accommodate the polarizations. We then use a
correction for the difference between the nominal MC@NLO

FIG. 1. The simulated $W +$ jets events before correction and
data with $\bar{t}t$ and other $W +$ jets background components
subtracted compared in $\cos \theta_{\ell,\hat{n}}$ distributions in the $\ell + 3$ jet
and no $b$ tagged jet control sample.

FIG. 2. Comparison of measured and generated polarizations
along the beam axis for the SM and several non-SM models. The uncertainties
are statistical.
production-level $A_{FB}$ of $(5.01 \pm 0.03)\%$ and the next-to-next-to-leading-order (NNLO) calculation [34] of $(9.5 \pm 0.7)\%$. The observed correction is $-0.030$ for the polarization along the beam axis, less than 0.002 for the polarization along the helicity axis, and is negligible for the transverse polarization. The uncertainty on the expected $A_{FB}$ is propagated to the measurement as part of the methodology systematic uncertainty.

V. SYSTEMATIC UNCERTAINTIES

We have evaluated several categories of systematic uncertainties using fully simulated events: uncertainties associated with jet reconstruction, jet energy measurement, $b$ tagging, the modeling of background and signal events, PDFs, and procedures and assumptions made in the analysis. The sources of systematic uncertainties and their contributions are listed in Table II and added in quadrature for the total uncertainty. Details about the evaluation of the uncertainties can be found in Refs. [21,31]. Additionally, we assign an uncertainty in modeling the invariant mass of the $t\bar{t}$ system ($m_{t\bar{t}}$) based on the difference in $m_{t\bar{t}}$ distributions in our signal MC and the NNLO predictions [35].

VI. RESULTS

The measured polarizations for the three spin-quantization axes are shown in Table III. Results on the longitudinal polarizations are presented in Fig. 4 and compared to SM predictions and several of the BSM models discussed previously. The measurement along the beam axis is consistent with the previous D0 result in the dilepton channel.

![Graphs showing experimental data and theoretical predictions for top quark polarization](https://example.com/graphs)

**TABLE II.** Summary of the uncertainties in the measured top quark polarization along three axes. The systematic uncertainty source indicates the difference in polarization when the measurement is repeated using alternative modeling, after applying uncertainties from the employed methods, or from assumptions made in the measurement. The uncertainties are added in quadrature to form groups of systematic sources and the total uncertainty.

We estimate the correlation between this result for the beam axis and that of Ref. [7] to be 5%. The combination using the method of Refs. [36,37] yields a top quark polarization along the beam axis $P = 0.081 \pm 0.048$.

VII. CONCLUSION

In summary, we measure the top quark polarization for $t\bar{t}$ production in $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV along several spin-quantization axes. The polarizations are consistent with SM predictions. The transverse polarization is measured for the first time. These are the most precise measurements of top quark polarization in $p\bar{p}$ collisions.

ACKNOWLEDGMENTS

We express our appreciation to Helen Edwards for her role in designing and building the Tevatron and her oversight of the D0 detector project in its early days. We thank R. M. Godbole and W. Bernreuther for enlightening discussions. We thank the staffs at Fermilab and collaborating institutions and acknowledge support from the Department of Energy and National Science Foundation (USA); Alternative Energies and Atomic Energy Commission and National Center for Scientific Research/National Institute of Nuclear and Particle Physics (France); Ministry of Education and Science of the Russian Federation, National Research Center “Kurchatov Institute” of the Russian Federation, and Russian Foundation for Basic Research (Russia); National Council for the Development of Science and Technology and Carlos Chagas Filho Foundation for the Support of Research in the State of Rio de Janeiro (Brazil); Department of Atomic Energy and Department of Science and Technology (India); Administrative Department of Science, Technology and Innovation (Colombia); National Council of Science and Technology (Mexico); National Research Foundation of Korea (Korea); Foundation for Fundamental Research on Matter (Netherlands); Science and Technology Facilities Council and The Royal Society (United Kingdom); Ministry of Education, Youth and Sports (Czech Republic); Bundesministerium für Bildung und Forschung (Federal Ministry of Education and Research) and Deutsche Forschungsgemeinschaft (German Research Foundation) (Germany); Science Foundation Ireland (Ireland); Swedish Research Council (Sweden); China Academy of Sciences and National Natural Science Foundation of China (China); and Ministry of Education and Science of Ukraine (Ukraine).
