The non-coding variant rs1800734 enhances DCLK3 expression through long-range interaction and promotes colorectal cancer progression

Ning Qing Liu¹,†, Menno ter Huurne¹, Luan N. Nguyen¹, Tianran Peng¹, Shuang-Yin Wang¹, James B. Studd², Onkar Joshi¹, Halit Ongen³, Jesper B. Bramsen⁴, Jian Yan⁵,⁶, Claus L. Andersen⁴, Jussi Taipale⁵, Emmanouil T. Dermitzakis³, Richard S. Houlston², Nina C. Hubner¹ & Hendrik G. Stunnenberg¹

Genome-wide association studies have identified a great number of non-coding risk variants for colorectal cancer (CRC). To date, the majority of these variants have not been functionally studied. Identification of allele-specific transcription factor (TF) binding is of great importance to understand regulatory consequences of such variants. A recently developed proteome-wide analysis of disease-associated SNPs (PWAS) enables identification of TF-DNA interactions in an unbiased manner. Here we perform a large-scale PWAS study to comprehensively characterize TF-binding landscape that is associated with CRC, which identifies 731 allele-specific TF binding at 116 CRC risk loci. This screen identifies the A-allele of rs1800734 within the promoter region of MLH1 as perturbing the binding of TFAP4 and consequently increasing DCLK3 expression through a long-range interaction, which promotes cancer malignancy through enhancing expression of the genes related to epithelial-to-mesenchymal transition.

†Present address: Division of Gene Regulation (B4), The Netherlands Cancer Institute, Plesmanlaan 121, 1066 CX, Amsterdam, The Netherlands. Correspondence and requests for materials should be addressed to N.Q.L. (email: n.liu@nkini.nl) or to H.G.S. (email: h.stunnenberg@ncmls.ru.nl).
A n individual’s risk to develop colorectal cancer (CRC) is affected by a broad spectrum of genetic variants that abolish the functions and/or alter the expression of target genes. In CRC, two types of genetic variants have been extensively discussed to contribute to disease onset and progression: (1) protein-coding mutations and (2) non-coding variants, in particular in DNA regulatory elements. To date, the majority of studies have focused on protein-coding mutations. Key coding mutations such as APC/CTNNB1, KRAS/BRAF, PIK3CA, TP53 and SMAD4 have been intensively characterized. However, even though a great number of non-coding risk variants for CRC have been identified in genome-wide association studies (GWAS)2–9, their molecular functions have rarely been determined.

Functional genetic variants in distal DNA regulatory elements may alter transcription networks in several ways such as by affecting transcription factor (TF) binding. Single-nucleotide polymorphisms (SNPs) within TF-binding sites may affect the local chromatin accessibility10–12 and/or alter the expression of gene targets through mediating different chromatin interactions13–15. Therefore, identification of variant-specific TF interactors is of great importance to understand regulatory consequences of the variants. However, DNA oriented methods such as DNase I sequencing (DNase I-seq)16, systematic evolution of ligands by exponential enrichment sequencing17 and chromatin immunoprecipitation with massively parallel DNA sequencing (ChiP-seq)18 are biased by DNA motif knowledge or limited by the availability of antibodies, resulting in a biased identification of TF-binding dynamics at disease-associated loci. A recently developed proteome-wide analysis of disease-associated SNPs (PWAS) enables to identify DNA–TF interactions in an unbiased manner19. A similar approach has been used to characterize a protein–DNA interaction map for ultra-conserved elements20. Therefore, we performed a large-scale PWAS study to comprehensively understand TF-binding landscape related to CRC.

As the outcome from our PWAS screen, we further investigated the functions of a SNP located in the promoter region of MLH1 gene (MLH1-93G>A or rs1800734), which has been associated with the risk of several cancer types including CRC9,21,22, endometrial cancer23, glioblastoma24 and lung cancer25. Here we identified a molecular function of this SNP in promoting cancer malignancy through a novel gene target named DCLK3.

**Results**

**PWAS identified specific interactors of rs1800734.** Our PWAS screen identified TFAP4 as an allele-specific interactor with an almost 16-fold higher affinity for G-allele, whereas ELF1 showed higher affinity for the A-allele of rs1800734 in LoVo cells (Fig. 1d). The A-allele abolishes TFAP4 binding due to a point mutation at the last position of the E-box (Fig. 2a), which simultaneously creates an E26 transformation-specific (ETS) family binding motif (Supplementary Fig. 2a). We corroborated and extended this finding by label-free-based DNA pulldown with SNU175 and COLO320 extracts (Fig. 2b and supplementary Fig. 2b). Notably, other basic helix-loop-helix (bHLH) and ETS family members also displayed allele-specific binding, including MYC and ELF2 (Supplementary Fig. 2b,c), indicating that these TFs can compete with TFAP4 and ELF1 at this locus. Using ChiP-seq as an orthogonal technique, we validated TFAP4 and ELF1 binding at the rs1800734 in the SNU175 and COLO320, cell lines heterozygous for this locus. Consistent with PWAS, TFAP4 ChiP-seq showed a dominant preference for G-allele binding in the two cell lines (Fig. 2c). ELF1 did not show significant allele-binding preference (Supplementary Fig. 2d), which may be due to the competitive binding interference by other ETS proteins.

**DCLK3 is a novel target of rs1800734.** Given the position of the SNP in the promoter of MLH1, we further investigated whether predisposition of rs1800734 in CRC is due to DNA methylation of MLH1 promoter as proposed9,30. We tested hypersensitivity and transcription of G- and A-allele in the two heterozygous cell lines, which showed the two alleles are equally accessible and transcribed (Fig. 2d). The neighbouring gene EPM2AIP1, also reported to be regulated by rs1800734 (ref. 31), was similarly unaffected by rs1800734 (Fig. 2d). Hence, we conclude that rs1800734 does not result in allele-specific epigenetic silencing of either MLH1 or EPM2AIP1 in these cell lines. We sought to confirm our observation in the Systems Biology of Colorectal Cancer (SYSCOL) cohort of paired healthy and tumour tissues (healthy: n = 288, tumour: n = 289). A strong expression quantitative trait loci (eQTL) between rs1800734 and MLH1 was observed in the healthy tissues (P = 0.001, linear regression model) but the A-allele was associated with increased MLH1 expression. This eQTL was lost in the tumours and remained only a weak association in microsatellite stable (MSS) tumours (P = 0.025, n = 236, linear regression model) (Supplementary Fig. 3a). Intriguingly, we identified a correlation between rs1800734 and DCLK3 expression in the healthy (P = 0.029, linear regression model)
Figure 1 | PWAS screen systematically identified allele-specific TF binding at the selected CRC risk loci. (a) Allele-specific binding of the 731 candidate TFs at the 116 CRC risk loci. Chromatin environment of the 116 SNPs was described by DHS of these loci in the 15 fetal large intestine tissues and 12 CRC cell lines, and histone modifications (H3K4me3, H3K4me1 and H3K27ac) within ±1 kb regions around these loci in the LoVo and HCT116 cell lines. The TFs with P-value \(< 10^{-30}\) and absolute Log2(fold change) > 3 was listed in the bubble plot. Bubble size represents \(-\log_{10}(P\text{-values})\) of the interactors in the pull-down screen (n = 2 pulldowns per SNP, P-values: A/B significance test). (b) Pathway annotation of the 731 TFs (HR, gonadotropin-releasing hormone receptor pathway; WNT/PDGF/Cholecystokinin/TGF-β, Wnt/PDGF/Cholecystokinin/TGF-β signalling pathways). (c) TF–SNP interactions ranked by fold changes in the PWAS screen and DHS at the SNP loci. Bubble size indicates the \(-\log_{10}(P\text{-values})\) of the TF–SNP interactions (n = 2 pulldowns per SNP, red and blue bubbles: P-value < 0.05, Z-test). (d) The top three candidate TF–SNP interactions (n = 2 pulldowns per SNP, red and blue dots: P-values < 0.01, A/B significance test).
Importantly, the eQTL association between rs1800734 and DCLK3 expression, two isogenic cell lines homozygous for G- or A-allele were generated from COLO320 using CRISPR-CAS9 technique (Fig. 3b) and the level of DCLK3 expression was replicated and a fivefold difference in DCLK3 expression was observed between G- and A-homozygotes (Fig. 3c). By sequencing the inter-exonic reverse transcriptase–qPCR products of DCLK3, we confirmed the transcription of DCLK3 in these cell lines (Supplementary Fig. 3d).

**Figure 2 | Identification of allele-specific interactors for rs1800734 and its potential gene targets.** (a) Motif analysis interpreted that A-allele of the locus perturbs E-box motif. (b) The specific binding of TFAP4 (P1 = 2.0 × 10⁻⁶, P2 = 3.1 × 10⁻⁵, P3 = 7.8 × 10⁻⁵, Student’s t-test) and ELF1 (P1 = 2.1 × 10⁻⁴, P2 = 0.011, P3 = 6.9 × 10⁻⁴, Student’s t-test) on G- and A-allele was observed in the three different cell lines (data are represented as mean and error bars indicate s.d., n = 3 pulldowns per SNP). ZFP62 binding on A-allele, as shown in Fig. 1d, was not consistent in all the three cell lines and was hence not considered as the general TF regulator at this locus. (c) This allele-specific binding was validated by ChIP-seq of TFAP4. This SNP did not change (d) the local chromatin accessibility and the expression of two cis-regulated genes (MLH1 and EPM2AIP1) (G (G-allele) and A (A-allele) of rs1800734, wt (wild-type allele) and del (deletion allele) of rs35149869, P-values: Fisher’s exact test). (e) eQTL analysis revealed a novel gene targets DCLK3 of this SNP (P-values were calculated in FastQTL software based on linear regression model).

and tumour (P = 0.031, linear regression model) samples, and this association was highly significant in the MSS patients (P = 0.004, linear regression model) (Fig. 2e), indicating this locus may act as a distal enhancer and regulate DCLK3.

The A-allele positively regulates transcription of DCLK3. To establish the functional relation between rs1800734 and DCLK3 expression, two isogenic cell lines homozygous for G- or A-allele were generated from COLO320 using CRISPR-CAS9 technique (Fig. 3a). Successful targeting of rs1800734 was confirmed by Sanger sequencing (Fig. 3b). No other mutation was observed in the surrounding region. ChIP–quantitative PCR (qPCR) confirmed higher TFAP4 binding to the G-allele (Supplementary Fig. 3b) and the level of MLH1 and EPM2AIP1 transcription was identical in the three isogenic lines (Supplementary Fig. 3c). Importantly, the eQTL association between rs1800734 and DCLK3 expression was replicated and a fivefold difference in DCLK3 expression was observed between G- and A-homozygotes (Fig. 3c). By sequencing the inter-exonic reverse transcriptase–qPCR products of DCLK3, we confirmed the transcription of DCLK3 in these cell lines (Supplementary Fig. 3d).

**rs1800734 regulates DCLK3 through long-range interactions.** A capture Hi-C study has suggested that rs3806624 in the promoter of EOMES affects AZI2, a gene 640 kbp downstream to this SNP, through a long-range chromatin interaction14. A similar constellation may apply to rs1800734. Therefore, Circularized Chromosome Conformation Capture with massively parallel DNA sequencing (4C-seq) was employed to search for long-range interactions between rs1800734 and other potential targets in the three isogenic cell lines. Using rs1800734 as a view point, a significantly enhanced interaction was observed in A-homozygote models. The specific binding of TFAP4 (P1 = 2.0 × 10⁻⁶, P2 = 3.1 × 10⁻⁵, P3 = 7.8 × 10⁻⁵, Student’s t-test) and ELF1 (P1 = 2.1 × 10⁻⁴, P2 = 0.011, P3 = 6.9 × 10⁻⁴, Student’s t-test) on G- and A-allele was observed in the three different cell lines (data are represented as mean and error bars indicate s.d., n = 3 pulldowns per SNP). ZFP62 binding on A-allele, as shown in Fig. 1d, was not consistent in all the three cell lines and was hence not considered as the general TF regulator at this locus. (c) This allele-specific binding was validated by ChIP-seq of TFAP4. This SNP did not change (d) the local chromatin accessibility and the expression of two cis-regulated genes (MLH1 and EPM2AIP1) (G (G-allele) and A (A-allele) of rs1800734, wt (wild-type allele) and del (deletion allele) of rs35149869, P-values: Fisher’s exact test). (e) eQTL analysis revealed a novel gene targets DCLK3 of this SNP (P-values were calculated in FastQTL software based on linear regression model).
with DCLK3 region (Fig. 3d). Increased interactions were found in the promoter and 3'-UTR region of DCLK3 in two independent experiments (Fig. 3e) and, in addition, the 3'-UTR interaction appeared to increase chromatin accessibility (Fig. 3f). In conclusion, the A-allele of rs1800734 increases the DCLK3 transcription through increased chromatin interaction and enhanced chromatin accessibility.

**DCLK3 is a potential oncogenic and tumour progressive factor.**

DCLK3 is one of three doublecortin-like kinases (DCLK1, DCLK2 and DCLK3). In this family, DCLK1 has been shown to be a cancer stem cell marker in intestinal tumours. The molecular function of the DCLK3 has not been characterized in depth. We therefore performed gene set enrichment analysis (GSEA) to identify DCLK3-associated gene sets in the SYSCOL RNA sequencing (RNA-seq) cohort. Interestingly, we found that epithelial-to-mesenchymal transition (EMT)-related genes were highly correlated to the expression of DCLK3 in the healthy tissues (normalized enrichment score (NES) = 2.50), which was enhanced in the tumour samples (NES = 3.10) (Fig. 4a and Supplementary Table 2). Using a cutoff of NES at 2.00, we also identified gene sets that are preferentially enriched in the healthy versus tumour tissues (Supplementary Table 2), for example 'MYC targets' and 'G2/M checkpoint' gene sets were enriched in the healthy tissue, whereas 'Angiogenensis' and 'tumor necrosis factor alpha (TNFA) signalling via nuclear factor–κB' gene sets were enriched in the tumour tissues (Fig. 4a). As expected, common EMT markers such as CALD1, FN1, SNAI1, SNAI2, TWIST1, VIM, ZEB1 and ZEB2 were highly significantly co-expressed with DCLK3 in the tumours (Fig. 4a), indicating that DCLK3 is an EMT regulator. Furthermore, we observed elevated DCLK3 expression in the tumour compared with healthy tissues (P = 2.2 × 10^-16, Mann–Whitney U-test) (Fig. 4b), but no difference between the microsatellite instable (MSI) and microsatellite stable (MSS) tumours (Fig. 4b). Interestingly, this elevation appeared to be correlated with the CRC progression: DCLK3 expression was at a comparable level in the healthy and adenoma tissues, and increased 2-fold in the stage I tumours (P = 2.2 × 10^-16, Kruskal–Wallis test) (Fig. 4b). Therefore, DCLK3 may promote EMT events and consequently drive tumour malignancy.
Discussion

Our study generated the first TF–SNP interaction map at presumed disease-relevant loci of CRC and determined TF-binding occupancy at the 116 upmost relevant CRC risk loci. Together with GWAS and epigenetic profiling data, our PWAS screens provide a comprehensive TF-binding landscape of these loci and yielded candidate interactions for further functional investigations (Fig. 1a,c,d and Supplementary Fig. 1d,e). As an
alternative approach to investigate allele-specific TF-binding events, the PWAS approach shows several advantages over the DNA-centric methods. In contrast to ChIP-seq technique, PWAS-based identification is a hypothesis-free approach, which does not require any knowledge on the possible binding TFs at risk loci. In addition, application of PWAS approach is not limited by the availability of high-quality ChIP-grade antibodies. Even though large ChIP-seq data sets have been generated, these data nevertheless cover only a small proportion of the entire repertoire of TFs. Other DNA-centric methods, such as DNease I-seq or assay for transposable-accessible chromatin with high throughput sequencing (ATAC-seq), are only capable of identifying DNA motifs present at risk loci, which makes it difficult to predict actual binding TF(s) from a family sharing similar motifs in a specific cell type. The outcome of PWAS is a reflection of TF abundance, TF ability to bind to the sequence (affinity), as well as synergistic and antagonist effects due to binding of other TFs to adjacent or overlapping sequences. Therefore, actual binding TFs in a given cell type can be predicted using PWAS method. In addition, PWAS approach allows to identify binding TFs at the loci only partially matching consensus motif sequences and therefore cannot be predicted by motif prediction-based methods. Based on the PWAS screen, we investigated in great depths for a well-known CRC-associated SNP: MLH1-93G>A or rs1800734. It has been postulated that A-allele (risk allele) of MLH1 is a well-known CRC-associated SNP: -93G>A, which subsequently results in promoter methylation of the MLH1 gene, supported by an association between the A-allele of the rs1800734 locus and the MLH1 promoter methylation. However, Suter et al. showed contradictory results that A-allele of this SNP is associated with lower promoter methylation and higher transcription of MLH1. Our results suggested that TFAP4 preferentially binds to T-allele of the rs1800734 but does not change promoter accessibility and transcription of MLH1.

Methods

Cell culture and extraction of nuclear soluble fraction. Human CRC cell lines were cultured in DMEM or RPMI medium supplemented with 10% fetal bovine, 100 U ml⁻¹ penicillin and 100 µg ml⁻¹ streptomycin. LoVo and SNU175 cell lines were purchased from American Type Culture Collection and Korean Cell Line Bank (KCLB), respectively. ACOLO320 cell line was a generous gift of Dr Riccardo Fodde (Erasmus Medical Center Rotterdam, The Netherlands), which is originally from American Type Culture Collection. The authenticity of the cell lines were confirmed using microsatellite short tandem repeat (STR) assay by the suppliers of the cell lines. Mycoplasma infection was routinely tested in-house, to ensure that all the cell lines used for this study were free of mycoplasma contamination.

High-throughput DNA pulldown. High-throughput DNA pull-down experiments were performed on 96-well filter plate format using our published method with minor modifications. To synthesize biotinylated double-stranded DNA (dsDNA) oligos, we attached a non-genomic 15 bp sequence at the 3'-end of the anti-sense strands. Subsequently, a reverse complement biotinylated primer was used to extend single-stranded DNA templates into dsDNA oligos. For each synthesis, 130 pmol of the biotinylated primer and 200 pmol template were subjected to a PCR reaction using Herculase II Fusion Enzyme kit under the following conditions: 95 °C for 3 min, 35 cycles (n = 20) at 95 °C for 1 min, 45 °C for 1 min and 72 °C for 1 min; 72 °C for 3 min; infinite hold at 12 °C. Briefly, high-throughput DNA pulldown was performed using a Multiscreen filter plate with 1.2 µm pores (Millipore, MSBV1210). The biotinylated dsDNA oligos were immobilized on 20 µl of high-performance streptavidin sepharose (GE Healthcare, 17511301). Two-hundred and fifty micrograms of nuclear extracts and 15 µg of competitors (5 µg of poly(deoxyinosinic-deoxycytidylic) acid sodium salt (Sigma-Aldrich, P4929), poly(deoxyadenylic-deoxymydidylic) acid sodium salt (Sigma-Aldrich, P0883) and Bakers yeast RNA (Sigma-Aldrich, R67520)) were added and incubated with immobilized oligos for 1.5 h at 4 °C on a plate shaker for each of the pull-down experiments. The components of the competitors were sonicated into ~300 bp fragments before use. The proteins unbound to DNA oligos were washed off using different washing buffers and the bound TFs were on-bead digested overnight using trypsin/LysC. The pull-down duplicates underwent dimethyl label swapping and measured by nanoscale liquid chromatography tandem mass spectrometry (LC-MS/MS) in a 2 h gradient.

Nuclear extract proteome. Deep proteome profile was generated from the nuclear extracts used for the pull-down experiments. An absolute quantification strategy was taken following a published method with minor modifications. To synthesize biotinylated double-stranded DNA (dsDNA) oligos, we attached a non-genomic 15 bp sequence at the 3'-end of the anti-sense strands. Subsequently, a reverse complement biotinylated primer was used to extend single-stranded DNA templates into dsDNA oligos. For each synthesis, 130 pmol of the biotinylated primer and 200 pmol template were subjected to a PCR reaction using Herculase II Fusion Enzyme kit under the following conditions: 95 °C for 3 min, 35 cycles (n = 20) at 95 °C for 1 min, 45 °C for 1 min and 72 °C for 1 min; 72 °C for 3 min; infinite hold at 12 °C. Briefly, high-throughput DNA pulldown was performed using a Multiscreen filter plate with 1.2 µm pores (Millipore, MSBV1210). The biotinylated dsDNA oligos were immobilized on 20 µl of high-performance streptavidin sepharose (GE Healthcare, 17511301). Two-hundred and fifty micrograms of nuclear extracts and 15 µg of competitors (5 µg of poly(deoxyinosinic-deoxycytidylic) acid sodium salt (Sigma-Aldrich, P4929), poly(deoxyadenylic-deoxymydidylic) acid sodium salt (Sigma-Aldrich, P0883) and Bakers yeast RNA (Sigma-Aldrich, R67520)) were added and incubated with immobilized oligos for 1.5 h at 4 °C on a plate shaker for each of the pull-down experiments. The components of the competitors were sonicated into ~300 bp fragments before use. The proteins unbound to DNA oligos were washed off using different washing buffers and the bound TFs were on-bead digested overnight using trypsin/LysC. The pull-down duplicates underwent dimethyl label swapping and measured by nanoscale liquid chromatography tandem mass spectrometry (LC-MS/MS) in a 2 h gradient.
digestion was quenched by a step buffer (50 mM Tris-HCl pH 8.0, 100 mM NaCl, 0.1% SDS, 100 mM EDTA pH 8.0, 1 mM Spermidine and 0.5 mM Spermine). A 9% Sucrose gradient was applied to fractionate the samples for 24 h at 25,000 rpm at 16°C and the fractions with <1 kb fragments were further purified and prepared according to the Illumina library preparation protocol.

DNase I library of other cell lines were prepared using a published protocol18 as described below. The cell lines were harvested under the confluence of 60% and washed with PBS. Nuclei were isolated with RSB lysis buffer (10 mM Tris-Cl pH 7.4, 10 mM NaCl, 3 mM MgCl2, 0.1% IGEPA CA-630) at 4°C for 10 min. Then the nuclei were treated with 0.12 unit of DNase I (Roche) in the provided buffer at 37°C for 15 min before being quenched by 50 mM of EDTA. Following RNase A (Sigma) treatment at 37°C for 15 min, proteinase K (NEB) was added for an additional hour at 56°C. DNA was extracted using phenol:chloroform; isoamylalcohol. Agarose Gel (2%) electrophoresis was applied to separate the released fragments (~100 bp) that were purified (Qiagen, MinElute Gel Extraction Kit), followed by Illumina TrueSeq library preparation and Sequencing (HiSeq2000).

ChIP-seq and ChiP-qPCR analysis. ChIP assays were performed following a standard protocol. Cell lines were cross-linked by a final concentration of 1% paraformaldehyde for 10 min and subsequently cross-linking reaction was quenched using 1.5 M glycine. The harvested cell lines were then lysed and sonicated to obtain ~300 bp chromatin using Bioruptr Plus sonication device (Diagenode). The sonicated chromatin was pre-cleaned by Protein A/G magnetic beads (ThermoFisher Scientific, 88802) and then incubated together with antibody conjugated beads overnight at 4°C. Antibodies against H3K27ac (Diagenode, CL51406) and H3K4me3 (Abcam, ab6005) were used. Nuclei were isolated in a 50 ml of lysis buffer (10 mM Tris-HCl pH 8.0, 10 mM NaCl, 3 mM MgCl2 and 0.1% IGEPA CA-630) detergent and quenched as in ChIP assays. TFAP4 (Santa Cruz Biotechnology, sc-631X, 4 μg per ChIP assay) were used in our ChIP experiments. Subsequently, the captured chromatin was washed, eluted and de-crosslinked. Resulted DNA fragments were purified and prepared according to Illumina library preparation (H3K27ac ChiP) or KAPA Hyper Prep (TFAP4 and ELF1 ChiP) protocols before sequencing, or directly quantified using SYBR Green-based qPCR arrays (Supplementary Table 3).

ATAC-seq analysis. ATAC libraries of the SNU175 and COLO320 cell lines were prepared by a documented protocol48 with some modifications. In brief, nuclei were isolated using a lysis buffer consisting of 10 mM Tris-HCl pH 7.5, 10 mM NaCl, 3 mM MgCl2 and 0.1% IGEPA CA-630 detergent and then tagmented49 using 2 μl of Tn5 transposase and 12.5 ul 2 × TD buffer (Illumina, Nextera DNA Library Preparation Kit). The resulted DNA fragments underwent two sequential nine-cycle PCR amplification, and in between two PCR reactions the libraries were selected for <600 bp fragments using SPRI beads. The final PCR products were purified and quantified by KAPA Library Quantification Kits before sequencing.

Targeted RNA-seq and reverse transcriptase-qPCR. Total RNA was isolated from the SNU175 and COLO320 cell lines using a TRIzol reagent (ThermoFisher Scientific, 15596018) based method. The yielded RNA was treated with DNase and then reversely transcribed into cDNA using random hexamers (ThermoFisher Scientific, 4180802). CT values of the targeted primers were determined following standard KAPA Hyper Prep protocols, or directly quantified using SYBR Green-based qPCR assays (Supplementary Table 3).

CrisPR-Cas9-based SNP editing. CRISPR-Cas9 based SNP editing were performed according to a previously reported method50. Single guide RNAs (sgRNAs) were designed using an online tool (http://crispr.mit.edu/) and double-nicking strategy was taken to reduce undesired off-target mutagenesis. The sgRNAs were then cloned into a U6-driven plasmid containing a green fluorescent protein (GFP) marker and the D10A mutant Cas9 nickase (Addgene, pSpCas9(2A)-GFP, Plasmid 48140). The plasmid was then transformed into the DH5α competent Escherichia coli strain and the products were purified for subsequence. Subsequently, the sgRNAs (400 ng each) and a 199 bp single-stranded oligonucleotides (10 pmol single-stranded oligo donor/sODNs (ssODNs), possessing G or A point mutations at the positions that were transected into COLO320 cell lines following a standard lipofectamine LT Reagent protocol (ThermoFisher Scientific, 15338100). FACs analysis was used to sort 192 GFP-positive cells per cell line (G or A point mutations) into 96-well plates in 36 h after the transfection. In parallel, a wild-type cell line was treated in the same manner by without using sgRNAs, and this mocked cell line was then sorted by FACs and served as the control. The desirable genotype at the rs1800734 was confirmed by Sanger sequencing. The oligos (sgRNAs and Single-Stranded Oligo Donors (sODNs)) used in these experiments were listed in Supplementary Table 3.

SNP genotyping. SNP genotyping was performed by a standard Sanger sequencing-based method. The regions containing mutations were PCR amplified using 2 μl of Tris-HCl pH 7.5, 10 mM NaCl, 0.2% IGEPA CA-630 detergent and 1 μx pro tease inhibitors). Subsequently, the nuclei were digested with 420 U T4 ligase (New England Biolabs Inc., R0215S) followed by an overnight in-nuclear ligation with 4,000 U T4 ligase (New England Biolabs Inc., M0202D) at 16°C. The ligated DNA was crosslinked, purified, digested with 90 U HpyC18III enzyme (New England Biolabs Inc., R0639S) and circularized with 5,000 U T4 ligase. The circularized DNA (16 × 300 ng) was amplified with bait-specific inverse primers (Supplementary Table 3), pooled and purified, followed by KAPA Hyper Prep protocols.

Proteomics data processing. Recorded mass spectrometric (MS) files were analysed by MaxQuant software (version 1.3.5.7)52 using standard settings for dimethyl or dimethoxy labelling. The quantification analysis were performed with Swiss/Protein human database (generated from version 06-2012). Batch effects of the pull-down data were removed using ‘Combat’ algorithm53. In dimethyl analysis, some proteins were consistently quantified in the pulldowns of only one allele (Ref- or Alt-allele) in two replicate experiments and the protein ratios can therefore not be obtained from MaxQuant output. Therefore, we imputed the missing value in these pulldowns using ‘Replace missing values from normal distribution’ option in Perseus software (version 1.3.9.18)54, which allows to further calculate protein ratios and perform downstream analysis. TF interactors for each of the pulldowns were identified using ‘Significance B’ function in Perseus software.

DNase I-seq ChiP-seq ATAC-seq data processing. Read mapping was performed using BWA-MEM (DNase I-seq) and BWA-MEM (ATAC-seq)55 against the hg19 reference human genome. PCR duplicates were removed for further data analysis. Peak calling was carried out using MACS2 (ref. 56) with default settings, except H3K27ac peaks were called using ‘broad’ option. Peaks were called at a q-value cutoff of 0.01. Overlapping peaks were merged for each of the different experiments before further analysis. Integrative Genomics Viewer57 was used to detect bi-allelic differential binding and hypersensitivity.

Targeted RNA-seq and RNA-seq data processing. Targeted RNA-seq data were mapped to the hg19 reference human genome using BWA-MEM55. Integrative Genomics Viewer57 was used to visualize the targeted RNA-seq data and detect bi-allelic differential expression. The SYSCOL RNA-seq cohort was mapped to the human reference genome sequence (GRCh37 autosomes + X + Y + M) using GEM mapper58. The reads with mapping quality <150 were excluded for further analysis. The genes were annotated using Ensemble 75. The reads of the genes were counted by ‘HTSeq’ framework59 and normalized using ‘DESeq’ package60.

Calculate significance of the TF–SNP interactions. Importance of the TF–SNP interaction in our screen was considered by combining DHS of the SNPs (read counts at the SNP position in 15 fetal large intestine tissues and 12 CRC cell lines) and the interaction strength (Log2(fold change) of a TF between Ref and Alt allele pulldowns). The detailed P-value calculation was performed using z-test based on following steps: (1) calculate average DHS (average DNase I-seq reads) of all the 116 loci in the DNase I-seq data from 15 fetal large intestine tissues and 12 CRC cell lines, and then z-score transform the hypersensitivity data of these loci; (2) calculate absolute Log2(fold change) of every TF–SNP interaction between Ref and Alt alleles, and then z-score transform the absolute Log2(fold change) of all the interactions; (3) average the z-scores of DHS and absolute Log2(fold change), and convert the average z-scores into P-values based on normal statistical distribution.

eQTL analysis. The eQTL analysis was performed as described in a previous publication52. Germline genotypes of these patients were genotyped on the Illumina 25.5K Exome v1.0 and imputed to 1000 genomes phase 3 release using IMPUTE2. For cis-eQTL analysis, we normalized gene quantification separately for healthy and tumor samples. Technical covariates were removed using the PEER program61 and 20 PEER factors were used in normalization. The cis region was defined as ± 1 Mb from the transcription start site for each gene. The associations between genotypes and gene quantification were obtained using the FastQTL software53.

4C-seq data processing. A reduced genome was generated by extracting the sequences flanking the NLAIII restriction sites (30 bp on each strand from the NLAIII restriction sites to downstream) using the hg19 reference human genome in order to reduce the mappability of our 4C-seq data. Subsequently, the mappability of the reduced sequences from each strand was evaluated and the uniquely mappable NLAIII restriction sites were kept for downstream analysis. The reads from each library were parsed based on the bait-specific primer sequence and mapped to the reduced hg19 genome using BWA-ALN with the default parameters. A Bioconductor package ‘r3Cseq’ was used as an all-inclusive sliding window was used to test significant interactions and calculate interaction difference.
Pathway annotation and GSEA analysis. TFs binding differentially to the 116 loci were annotated to PANTHER pathways using PANTHER Classification System. GSEA analysis was applied to identify the gene sets correlated to DCLK3 expression. The search was performed against hallmark gene sets in Molecular Signatures Database (MSigDB, v5.1).

Data availability. Raw and processed LC-MS/MS data and sequencing data are available at ProteomeXchange [http://www.ebi.ac.uk/pride/] and Gene Expression Omnibus (https://www.ncbi.nlm.nih.gov/geo/) under the accession numbers PXD004435 and GSE83986, respectively. The publically available data used in this study were downloaded from Gene Expression Omnibus (https://www.ncbi.nlm.nih.gov/geo/) using the following accession numbers: (1) H3K4me1 and H3K4me3 ChIP-seq: GSM1240111, GSM453504, GSM1208880, GSM1208881; (2) DNase I-seq: GSM736493, GSM736600, GSM736590, GSM763687, GSM665815, GSM665818, GSM665826, GSM7011490, GSM7011495, GSM7011514, GSM7174231, GSM774214, GSM774214, GSM774224, GSM774232, GSM811762, GSM811788, GSM811798, (3) TF ChIP-seq: GSM1010902, GSM1208683, GSM1208684, GSM1208830, GSM1010847, GSM1208763, GSM1010765, GSM1010690, GSM1010852, GSM1208598, GSM791411, GSM791412, GSM798213, GSM1122306, GSM772208, GSM1122302, GSM1122303. The detailed information of in-house generated and public data sets used in this study are listed in Supplementary Table 4. All other remaining data are available within the article and Supplementary Information files, or available from the authors upon request.

Acknowledgements
This study was supported by the EU FP7 SYSCOL project. We gratefully thank Dr XiaoFei Zhang for sharing his knowledge on functional experiments, Ms Eva Janssen-Megens and Ms Bowon Kim for their sequencing service, and Dr Riccardo Fodde for providing the wild-type COLO320 cell line.

Author contributions
N.Q.L., N.C.H. and H.G.S. conceived and designed this study. N.Q.L., M.t.H., L.N.N., T.P. and O.J. performed the proteomics, genomics and cell biology experiments. N.Q.L., S.-Y.W., J.B.S., H.O., E.T.D., R.S.H. and N.C.H. carried out statistical and bioinformatics analyses. J.B.B. and C.L.A. provided the SYSCOL RNA-seq data, and J.Y. and J.T. provided some sequencing data of the LoVo cell line for this study. H.G.S. supervised the whole study. N.Q.L. and H.G.S. drafted the manuscript, which was reviewed by all the authors.
