Deletions and mutations affecting lymphoid transcription factor IKZF1 (IKAROS) are associated with an increased relapse risk and poor outcome in B-cell precursor acute lymphoblastic leukemia. However, additional genetic events may either enhance or negate the effects of IKZF1 deletions on prognosis. In a large discovery cohort of 533 childhood B-cell precursor acute lymphoblastic leukemia patients, we observed that single-copy losses of BTG1 were significantly enriched in IKZF1-deleted B-cell precursor acute lymphoblastic leukemia (P=0.007). While BTG1 deletions alone had no impact on prognosis, the combined presence of BTG1 and IKZF1 deletions was associated with a significantly lower 5-year event-free survival (P=0.0003) and a higher 5-year cumulative incidence of relapse (P=0.005), when compared with IKZF1-deleted cases without BTG1 aberrations. In contrast, other copy number losses commonly observed in B-cell precursor acute lymphoblastic leukemia, such as CDKN2A/B, PAX5, EBF1 or RB1, did not affect the outcome of IKZF1-deleted acute lymphoblastic leukemia patients. To establish whether the combined loss of IKZF1 and BTG1 function cooperate in leukemogenesis, Btg1-deficient mice were crossed onto an Ikzf1 heterozygous background. We observed that loss of Btg1 increased the tumor incidence of Ikzf1+/− mice in a dose-dependent manner. Moreover, murine B cells deficient for Btg1 and Ikzf1+/− displayed increased resistance to glucocorticoids, but not to other chemotherapeutic drugs. Together, our results identify BTG1 as a tumor suppressor in leukemia that, when deleted, strongly enhances the risk of relapse in IKZF1-deleted B-cell precursor acute lymphoblastic leukemia, and augments the glucocorticoid resistance phenotype mediated by the loss of IKZF1 function.
**Introduction**

Acute lymphoblastic leukemia (ALL) is the most common form of cancer in children and is characterized by recurrent genetic aberrations and chromosomal abnormalities, which represent distinct genetic subtypes that are used for risk stratification. In the past, we and others have demonstrated that genomic alterations affecting the lymphoid transcription factor gene IKZF1 represent a strong prognostic factor associated with relapse in childhood B-cell precursor acute lymphoblastic leukemia (BCP-ALL). Recently, we established that loss of IKZF1 affects glucocorticoid (GC)-mediated gene regulation and confers GC resistance in BCP-ALL. Deletion of IKZF1 is a hallmark of BCR-ABL1-positive BCP-ALL, and within this high-risk cytogenetic subtype, IKZF1 loss is associated with an even worse outcome. IKZF1 gene lesions are also frequently present in high-risk leukemias with a Philadelphia- or BCR-ABL1-like expression signature, which often carry activated tyrosine kinases (i.e., ABL1, PDGFRB, JAK2, FLT3) or mutations targeting the RAS path way. Mouse studies have confirmed that two of these genomic alterations, namely BCR-ABL1 and mutant RAS, cooperate with loss of IKZF1 during leukemic transformation. On the other hand, ERC gene deletions constitute a specific subtype of BCP-ALL with favorable outcome, despite the frequent co-occurrence of IKZF1 deletions. Thus, specific genetic interactions may modulate the tumor suppressive functions of IKZF1 during leukemic development at initial diagnosis and at relapse after chemotherapy treatment.

Besides IKZF1, many other recurrent genetic aberrations have been observed in BCP-ALL, which include deletions affecting BTG1, CDKN2A/B, EBF1, ETV6, PAX5, RAG4, RB1 and TCF3. For some of these co-occurring genetic lesions, synergistic effects have been reported on leukemia development. For example, loss of Rag1 was shown to accelerate the onset of B-cell lymphoblastic leukemia in Cdkn2a/p19Arf-deficient mice, while increasing the incidence of T-cell lymphomas in Tcf3−/− mice. Furthermore, combined heterozygosity for Ebf1 and Pax5 results in a strong increase in the frequency of pro-B-cell leukemia in mice.

Herein we describe the impact of deletions affecting the transcriptional coregulator B-cell translocation gene 1 (BTG1), in co-occurrence with IKZF1 loss on both leukemogenesis as well as outcome. We demonstrate that BTG1 deletions are enriched in IKZF1-deleted pediatric BCP-ALL cases, and correlate with increased relapse risk in this patient group. Using mouse knockout models, we further demonstrate that loss of Btg1 cooperates with Ikzf1−/− in the onset of ALL. Finally, our data indicate that both BTG1 and IKZF1 are important determinants of the GC therapy response, and that combined loss of these tumor suppressors enhances GC resistance.

**Methods**

**Clinical samples**

The discovery cohort comprised of 533 pediatric patients with newly diagnosed BCP-ALL from three consecutive Dutch Childhood Oncology Group trials (DCOG ALL-8, ALL-9 and ALL-10) and two German Cooperative ALL trials (COALL 06-97 and 07-08). The validation cohort consisted of 515 pediatric patients enrolled in the Australian and New Zealand Children’s Haematology and Oncology Group (ANZCHOG) ALL8 protocol. In accordance with the Declaration of Helsinki, written informed consent was obtained from parents or legal guardians, and institutional review boards approved the use of excess diagnostic material for research purposes. Details on the patient cohorts, treatment regimens and outcomes, were described previously.

**Statistics patient data**

Cumulative incidence of relapse (CIR) was estimated using a competing risks model, equality of CIRs was tested with Gray’s test. Relapse and non-response to induction chemotherapy were considered as events, with death and secondary malignancy as competing events. Event-free survival (EFS) was calculated with non-response, relapse, secondary malignancy and death considered as events. EFS probabilities were estimated using the Kaplan-Meier method, and survival data between groups were compared using univariate and multivariate Cox regression analyses. The proportions of patients with IKZF1 and other B-cell development gene deletions as well as other categorical variables were compared using the Fisher’s exact test. All P-values are two-sided, and a significance level of 0.05 or less was considered to be significant. Analyses were performed in R 3.0.1 (2013-05-16), using the packages cmprsk version 2.2-7, mstate version 0.2.7, and survival version 2.37-4.

**Mice**

Btg1 and Ikzf1 (Ikz10) knockout lines have been described previously and were intercrossed on a C57Bl6/J background. Mice were maintained under specific pathogen-free conditions at our Central Animal Laboratory facility. Genotyping of the offspring was performed by polymerase chain reaction (PCR) (primer sequences are listed in the Online Supplementary Table S1). Animal experiments were approved by the Animal Experimental Committee of the Radboud university medical center and were performed in accordance with institutional and national guidelines.

**Functional characterization of murine lymphocytes**

Detailed information on functional characterization of normal and leukemic lymphocytes by flow cytometry, immunohistochemistry, immunoglobulin (IG)/T-cell receptor (TR) PCR and cell viability assays can be found in the Online Supplementary Methods section. To analyze the glucocorticoid response in B lymphocytes, mononuclear splenocytes were isolated from wild-type and the different knockout mice, and stimulated in vitro with 5 μg/mL lipopolysaccharide (LPS) for 48 hours. The obtained activated B lymphocytes (± 80% R20%) were isolated by ficoll gradient and cultured for another 48 hours in the absence or presence of the synthetic glucocorticoids prednisolone or dexamethasone. Thereafter, relative cell viability was assessed by MTS assay and AnnexinV/7-AAD staining.

**Results**

**BTG1 deletions are enriched in IKZF1-deleted pediatric BCP-ALL**

Gene deletion of the tumor suppressor IKZF1, creating either dominant-negative IKZF1 isoforms or haploinsufficiency, is an important predictor of poor outcome in BCP-ALL, but to what extent other additional common single gene deletions, such as CDKN2A/B, PAX5, BTG1, ETV6, EBF1 or RB1 impact the prognostic value of IKZF1 has not been clearly established. To address this question, we studied a previously described childhood BCP-ALL cohort
of 533 cases enrolled in consecutive DCOG and COALL trials. The representation of the different BCP-ALL subtypes was similar between the DCOG and COALL cohorts, and comparable to that described in the literature (Online Supplementary Table S2). We identified 105 BCP-ALL patient samples containing an IKZF1 deletion. Within the IKZF1-deleted group, we observed a significant enrichment for BTG1 deletions (P=0.007), where 17 of the 105 IKZF1-deleted cases (16%) harbored BTG1 deletions as compared to 31 of the 428 IKZF1 wild-type cases (7%) (Table 1). These focal BTG1 deletions mainly covered the second exon of BTG1 and downstream adjacent sequences, as described previously. Similarly, deletions affecting PAX5 (P<0.0001), CDKN2A/B (P=0.0008) and RB1 (P=0.026) were present at higher frequencies in IKZF1-deleted cases, whilst this was not observed for EBF1 or ETV6 deletions (Table 1). To the contrary, in the BTG1-deleted group we observed significant enrichment for IKZF1 (P=0.007), EBF1 (P=0.0011), RB1 (P=0.042), and ETV6 (P=0.0046) deletions (Online Supplementary Table S3), which is in agreement with our previous findings. Previously, it has been shown that both IKZF1 and BTG1 deletions are strongly enriched in the cytogenetic BCR-ABL1 subtype. Consistent with this notion, we observed that 24 BCR-ABL1-positive cases, 7 (29%) harbored deletions in both IKZF1 and BTG1 (Table 2), which represents 47% of IKZF1-deleted and 100% of the BTG1-deleted cases found in the BCR-ABL1-positive group (Table 2).

Combined deletions of BTG1 and IKZF1 predict inferior outcome in BCP-ALL

We next compared clinical characteristics of BTG1;IKZF1 double-deleted cases, sole deletion of IKZF1 and sole deletion of BTG1 cases, and cases without IKZF1 or BTG1 deletion in our complete childhood BCP-ALL cohort. The characteristics of these four groups were similar to the total cohort with respect to gender and treatment protocol (Table 2). The double-deleted and sole deletion of IKZF1 groups contained more patients over 10 years of age and increased white blood cell counts, and hence more National Cancer Institute (NCI)-Romé criteria high-risk cases (Table 2). We compared the EFS and CIR between cases with both IKZF1 and BTG1 deletions (BTG1-del;IKZF1-del, n=17) with the cases of sole deletion of IKZF1 (BTG1-wt;IKZF1-del, n=88) (Figure 1A,B). The 5-year CIR in IKZF1- plus BTG1-deleted cases was 53% ± 13% compared with 28% ± 5% in the cases of sole deletion of IKZF1 (P=0.005; Table 3A). Similarly, the 5-year EFS was lower in double-deleted cases compared with the cases of sole deletion of IKZF1 (HR 3.5, P=0.0003; Table 3A). In contrast, the cases of sole deletion of BTG1 (BTG1-del;IKZF1-wt, n=31) showed a similar outcome (5-year CIR:10% ± 6%) to the reference cases without IKZF1 or BTG1 deletions (n=397; 5-year CIR:15% ± 2%). The synergistic effect of loss of BTG1 and IKZF1 on outcome remained after correction for subtype in the Cox model (Table 3A), and after leaving out the BCR-ABL1-positive cases (Figure 1C,D; Table 3B). For the BCR-ABL1-positive cases, BTG1 deletions did not further impact the poor treatment outcome as observed for the cases of sole deletion of IKZF1 (Figure 1E,F; Table SC).

As deletions of PAX5, CDKN2A/B and RB1 were similarly enriched in IKZF1-deleted BCP-ALL, we examined the impact of these deletions on the outcome of IKZF1-deleted cases. In contrast to BTG1, IKZF1 double-deleted patients, the outcome of patients with co-occurring PAX5, CDKN2A/B or RB1 deletions did not differ from cases of sole deletion of IKZF1 (Figure 2; Online Supplementary Table S4). Similarly, co-occurrences of IKZF1 deletions with either EBF1 or ETV6 deletions did not affect outcome compared with the sole deletion of IKZF1. To validate our findings, we analyzed the Australian and New Zealand ANZCHOG ALL8 cohort (n=155) to assess the prognostic value of BTG1;IKZF1 double-deletions. In this cohort, 6 out of 11 BTG1-del;IKZF1-del patients developed a relapse (Online Supplementary Figure S1). The 5-year CIR in the BTG1;IKZF1 double-deleted group was 61% ± 19% versus 35% ± 6% in the group with the sole deletion of IKZF1 (P=0.19; Table 3D). Hence, the same trend was observed in this independent validation cohort, albeit statistically non-significant. Together, these data indicate that BTG1 deletions in an unselected leukemia population have no prognostic value, but BTG1 copy number losses specifically exacerbate the effects of IKZF1 deletion on inferior outcome in BCP-ALL.
Leukemia predisposition in $Btg1$ knockout mice

Although deletions affecting the $BTG1$ gene are a frequent event in BCP-ALL, a direct role for $BTG1$ in leukemia development has not been reported. Therefore, we first examined the tumor suppressive function of $BTG1$ using a constitutive $Btg1$ knockout line harboring a Neo-cassette in the first coding exon.28 We previously reported that these $Btg1$ knockout mice display defective B-cell development with a 25% reduction in the amount of progenitor B cells within the bone marrow compartment, mainly affecting the pre-B and immature B-cell stage.33 Furthermore, $Btg1$ is required for optimal proliferative expansion of early progenitor B cells in methylcellulose in response to interleukin-7. At the same time, there was no obvious defect in the development of myeloid and T-lymphoid cells in these $Btg1$-deficient animals.33 In the study herein, mice that carried either one or two copies of the $Btg1$ knockout allele were followed over a period of 18 months, along with control littermates. About 6% (n=3/49) of the wild-type $C57BL/6J$ mice developed B-cell lymphomas between the age of 14 and 18 months (Table 4), which is consistent with previous observations.34 Within the same time period 6% of the $Btg1^{+/−}$ (n=2/34) and 18% of the $Btg1^{-/-}$ (n=6/33) mice developed T-cell leukemia exclusively (Table 4), characterized by enlarged primary lymphoid organs, such as the spleen and lymph nodes, and focal infiltration of leukemic T cells into peripheral organs, such as the lungs and liver. These $Btg1$-deficient T-cell leukemias expressed the T-cell surface marker CD44, and displayed clonal T-cell receptor (TR) rearrangements (Figure 3B). In addition, these CD44− T-cell leukemias not only showed increased expression of the T-cell activation marker CD44, but also large numbers of B220+ cells within the infiltrated areas of tissues, such as the liver or lungs, and affected lymph nodes (Online Supplementary Figure S2). There was no evidence for clonal immunoglobulin gene rearrangements in these $Btg1^{−/−}$ T-cell leukemias (Online Supplementary Figure S2), suggesting the presence of a substantial number of non-malignant B lymphocytes in proximity to these leukemic T cells. These data show that, although somatic $BTG1$ deletions predominantly occur in BCP-ALL, $Btg1$-deficiency in the mouse germline predisposes exclusively to T-cell malignancies. This predilection for T-lineage leukemias is also observed in other knockout mouse models targeting genes commonly deleted in BCP-ALL, such as $Ikzf1$ mutant mice.35,36

Loss of $Btg1$ increases leukemia incidence in $Ikzf1^{−/−}$ mice

To investigate cooperation between $BTG1$ and $IKZF1$ during leukemogenesis, we intercrossed $Btg1$-deficient mice with haplodeficient $Ikzf1$ mice using the $Ikzf1^{−/−}$ mouse line,29 which harbors a Neo-floxed knock-in allele combined with a Pax5-IRES-GFP complementary DNA (cDNA) at the first coding exon of $Ikzf1$, thereby creating an $Ikzf1^{−/−}$ null allele.29 These mice are only viable as a heterozygous knockout line ($Ikzf1^{−/+}$). First, we analyzed the phenotype of young animals (age 6-12 weeks) to assess the effect of the $Ikzf1^{−/−}$ allele on $Btg1$-deficiency in B- and T-lymphoid development. $Ikzf1^{−/−}$ mice, like $Btg1^{−/−}$ mice, displayed a moderate reduction in the fraction of B220+ cells in bone marrow (BM) and the spleen (Online

WBC count for 2 cases missing; NCI Risk for 1 case missing; both in the $BTG1$-wt, $IKZF1$-wt group: del: deletion; WBC: white blood cell; NCI-Rome HR: high-risk defined by age at diagnosis ≥10 years and/or WBC ≥50 cells/nl; HeH: high hyperdiploid (51-65 chromosomes); P-value: Fisher's exact test across the four deletions groups; wt: wild-type; DCOG: Dutch Childhood Oncology Group; COALL: German Cooperative ALL; SR: standard-risk.
This correlated with a partial block at the pre-pro-B-cell stage (Hardy fraction A) and the pre-B-cell stage (Hardy fraction D) in Ikzf1−/− mice (Online Supplementary Figure S3). BTG1−/−;Ikzf1−/− mice showed an even stronger reduction in B220+ cells, with additive effects at both B220+CD43+ and B220+CD43− differentiation stages in BM (Hardy fractions A to E) (Online Supplementary Figure S3). In contrast, BTG1−/−;Ikzf1−/− mice, similar to BTG1−/− and Ikzf1−/− single knockout animals, showed no major defects in postnatal thymic T-cell development (Online Supplementary Figure S4).

Next, we followed Ikzf1−/−, BTG1−/−;Ikzf1−/− and BTG1−/−;Ikzf1−/− mice for a period of 18 months. In our cohort, 14% (n=5/36) of the Ikzf1−/− mice developed T-cell leukemia between 3 and 18 months of age, with a median age of 12 months (Figure 3A; Table 4). Similar to BTG1-deficient leukemia, the Ikzf1−/− T-cell leukemias showed infiltration of CD3+ leukemic blasts into distant organs and clonal TR rearrangements (Figure 3). Interestingly, we observed an increased leukemia incidence upon combined loss of BTG1 and Ikzf1 (Figure 3A), which is consistent with our hypothesis that BTG1 deletions cooperate with IKZF1 aberration to induce human BCP-ALL. We found that 26% of the BTG1−/−;Ikzf1−/− mice (n=10/35) and 40% of the BTG1−/−;Ikzf1−/− mice (n=12/30) developed T-cell leukemia, while leukemias in BTG1−/−;Ikzf1−/− appeared with a slightly shorter latency (9.4 months) relative to Ikzf1−/− mice (12.4 months) (P=0.011) (Table 4). Tumors in the BTG1−/−;Ikzf1−/− compound mice were characterized by significantly higher leukocyte counts in peripheral blood compared to single knockout animals (Figure 3B,C), and strong infiltration of leukemic cells into the liver and lungs (Figure 3B,D), as well as clonal TR rearrangements (Figure 3E). Flow cytometric analysis of the different T-cell leukemias revealed

Supplementary Figure S3). This correlated with a partial block at the pre-pro-B-cell stage (Hardy fraction A) and the pre-B-cell stage (Hardy fraction D) in Ikzf1−/− mice (Online Supplementary Figure S3). BTG1−/−;Ikzf1−/− mice showed an even stronger reduction in B220+ cells, with additive effects at both B220+CD43+ and B220+CD43− differentiation stages in BM (Hardy fractions A to E) (Online Supplementary Figure S3). In contrast, BTG1−/−;Ikzf1−/− mice, similar to BTG1−/− and Ikzf1−/− single knockout animals, showed no major defects in postnatal thymic T-cell development (Online Supplementary Figure S4).

Next, we followed Ikzf1−/−, BTG1−/−;Ikzf1−/− and BTG1−/−;Ikzf1−/− mice for a period of 18 months. In our cohort, 14% (n=5/36) of the Ikzf1−/− mice developed T-cell leukemia between 3 and 18 months of age, with a median age of 12 months (Figure 3A; Table 4). Similar to BTG1-deficient leukemia, the Ikzf1−/− T-cell leukemias showed infiltration of CD3+ leukemic blasts into distant organs and clonal TR rearrangements (Figure 3). Interestingly, we observed an increased leukemia incidence upon combined loss of BTG1 and Ikzf1 (Figure 3A), which is consistent with our hypothesis that BTG1 deletions cooperate with IKZF1 aberration to induce human BCP-ALL. We found that 26% of the BTG1−/−;Ikzf1−/− mice (n=10/35) and 40% of the BTG1−/−;Ikzf1−/− mice (n=12/30) developed T-cell leukemia, while leukemias in BTG1−/−;Ikzf1−/− appeared with a slightly shorter latency (9.4 months) relative to Ikzf1−/− mice (12.4 months) (P=0.011) (Table 4). Tumors in the BTG1−/−;Ikzf1−/− compound mice were characterized by significantly higher leukocyte counts in peripheral blood compared to single knockout animals (Figure 3B,C), and strong infiltration of leukemic cells into the liver and lungs (Figure 3B,D), as well as clonal TR rearrangements (Figure 3E). that most of the $\text{Btg1}^{-/-};\text{Ikzf1}^{+/-}$ leukemias were CD4$^+$CD8$^+$ double positive T cells with ongoing differentiation towards CD4 or CD8 single positive stage (Figure 3F, Online Supplementary Table S5). Moreover, isolated leukemic T cells, derived from all the different genetic backgrounds included in our studies ($\text{Ikzf1}^{+/-}, \text{Btg1}^{-/-}$ and $\text{Btg1}^{-/-};\text{Ikzf1}^{+/-}$), could be serially transplanted into syngeneic C57BL6/J mice giving rise to similar (oligo)clonal T-cell leukemias (Online Supplementary Figure S5). Taken together, our data demonstrate that loss of $\text{Btg1}$ cooperates with haplodeficiency for $\text{Ikzf1}$ during mouse leukemia development in a dose-dependent manner.

Figure 1. Cumulative incidence of relapse (CIR) and event-free survival (EFS) curves for pediatric BCP-ALL cases with or without $\text{IKZF1}$ and $\text{BTG1}$ deletions. BTG1 modifies glucocorticoid resistance mediated by loss of IKZF1

While these experiments confirm the genetic interaction between BTG1 deletions and IKZF1 aberrations during leukemogenesis, they do not explain the poor outcome observed in patients showing a combined loss of BTG1 and IKZF1. Recently, we established that inferior outcome related to IKZF1 deletions in BCP-ALL is correlated with an attenuated in vivo day 8 prednisolone response and increased GC resistance in IKZF1-deleted primary leukemic cells, as determined by in vitro MTT assays. These results could be recapitulated using primary splenic B cells isolated from Izkf1-/- mice, which revealed that non-leukemic Izkf1-/- B cells are also less sensitive towards GC-induced apoptosis. Based on our previous findings that BTG1 regulates glucocorticoid receptor activation, we...
investigated whether loss of BTG1 would impact the GC response in primary murine B cells. To this end, B cells isolated from WT, Btg1+/−, Ikzf1−/+ and Btg1−/−;Ikzf1+/− mice, and obtained after lipopolysaccharide activation, were stimulated for 48 hours with increasing concentrations of prednisolone or dexamethasone and subjected to MTS assays to assess relative cell survival. While Btg1-deficiency alone had no effect on GC-induced apoptosis, Ikzf1-haplodeficient B cells showed enhanced cell survival as compared to WT (Figure 4A), similar to our previous findings. Importantly, Btg1−/−;Ikzf1+/− B cells showed an even stronger resistance to GC-induced apoptosis when compared to Ikzf1−/+ B cells (P<0.001). These findings were confirmed by AnnexinV staining, demonstrating a significantly smaller apoptotic fraction in Btg1−/−;Ikzf1−/+ B cells relative to Ikzf1−/+ B cells (P<0.001) (Figure 4B). Analyses of primary Btg1−−, Ikzf1−− and Btg1−−;Ikzf1−− thymocytes revealed no differential sensitivity to GC-induced apoptosis as compared to WT (Online Supplementary Figure S6A). Next, we assessed whether loss of Btg1 and Ikzf1 would promote resistance in B cells to other chemotherapeutic drugs commonly used in the treatment of BCP-ALL patients, including 6-mercaptopurine, doxorubicin, vincristine and asparaginase. However, Btg1−+;Ikzf1−+ and Btg1−−;Ikzf1−− B cells showed similar cell survival in comparison to control cells (Online Supplementary Figure S6B).

Together, these data argue that loss of tumor suppressor BTG1 enhances GC resistance in the context of IKZF1 deletions, which may explain the inferior treatment outcome observed in patients showing combined loss of BTG1 and IKZF1.

**Discussion**

BCP-ALL is a heterogeneous disease characterized by recurrent deletions enriched in specific genetic subtypes. For instance, it is known that deletions affecting the transcriptional co-regulator BTG1 are unevenly distributed among cytogenetic subgroups, as we and others have shown that BTG1 deletions are strongly enriched in ETV6-RUNX1-positive leukemia as well as BCR-ABL1-positive ALL. The presence of these lesions in such distinct BCP-ALL subgroups may relate to the fact that deletions of IKZF1 and BTG1 appear to be the result of illegitimate RAG recombination, as is the case for several of the other...
commonly deleted genes, such as EBF1 and PAX5. In addition to these earlier observations, we find a specific co-occurrence of BTG1 and IKZF1 gene deletions across cytogenetic subtypes, suggesting that the combined loss of BTG1 and IKZF1 may actively contribute to leukemogenesis. Previous studies, mostly carried out in mouse models, revealed that Ikaros and Arf alterations in BCR-ABL1-positive ALL synergize to promote the development of leukemia by conferring stem cell-like properties. This leads us to hypothesize that the preponderance of BTG1;IKZF1 double-deletions in this particular subgroup may have similar consequences, although this remains to be assessed in well-established BCR-ABL1-positive mouse models. As BTG1 and IKZF1 deletions also (co)occur in lymphoid blast crises of chronic myeloid leukemia (CML), it will be interesting to study if and how the lymphoid blast crises of chronic myeloid leukemia by conferring stem cell-like properties. This may have similar consequences, although this remains to be established in future studies. The relation between BTG1 deletions and inferior outcome was recently confirmed with the analyses of a relapsed BCP-ALL cohort, showing that BTG1 and NR3C1 deletions were associated with a higher risk of disease progression. Collectively, our data demonstrate that BTG1 is a prognostic factor and regulator of the GC response, particularly in the context of IKZF1-deletions.

Acknowledgments
The authors would like to thank Mariëtte von Lindern and Meinrad Busslinger for providing the Btg1 and Ikaros knockout mice, respectively. We would like to thank Arian van der Veer for performing the MLPA experiments.

Funding
This work was supported by grants of the Stichting Kinderen Kankervrij (KiKa 2009-55; KiKa 2010-77; KiKa 2014-132) and Stichting KOC Nijmegen. Work on the validation cohort was supported by NHMRC Australian APP1057746. MLJB has been supported by grants from the Dutch Cancer Society KWF (AMC 2008-4365), the Paediatric Oncology Foundation Rotterdam, the European Union’s Seventh Framework Program (FP7/2007-2013 ENCCCA grant HEALTH-F2-2011-261474); RPK and PH have been supported by grants from the Dutch Cancer Society KWF (KUN 2009-4298); EW is supported by a fellowship from the Dutch Cancer Society KWF.
