1. INTRODUCTION

The lambda calculus was originally conceived by Church as part of a general theory of functions and logic, intended as a foundation for mathematics. Although the full system turned out to be inconsistent, the subsystem dealing with functions only turned out to be a successful model of the computable functions. For an introduction to the subject and its relation to functional programming, see Barendregt [1990]. Some books on the lambda calculus are Barendregt [1984] and Hindley and Seldin [1986]. A major problem with the lambda calculus as functional programming language is the great amount of freedom in combining terms. A way to restrict this combinatorial freedom is the use of types, which are characterisations of classes of terms. The first type systems for lambda calculus were introduced in Curry [1934] and Church [1941]. Since then many typed lambda calculi have been proposed for different purposes.

The evolution of programming languages shows a similar pattern. The oldest varieties, like assembler and LISP, were essentially typefree and allowed too much combinatorial freedom. In languages like ALGOL 68 and Fortran simple but rather rigid type systems were introduced. For various applications these type systems were too restrictive and they have been extended in many ways. Type theory is currently an active research area. Publications, like the IEEE-LICS and ACM-POPL proceedings and papers like Cardelli and Wagner [1985] and Reynolds [1985], show that the developments in lambda calculi and programming languages are converging. It also displays a bewildering variety of systems and confusion of notations and nomenclature. What is clearly needed is a classification or taxonomy of these systems on the basis of a common frame of reference. This paper presents a contribution towards such a classification. The exposition is based on the extensive treatment in Barendregt [1999-], but because of space limitations proofs have been omitted. Although the paper concentrates on typed lambda calculi, at many places the relations with programming languages are illustrated.

The main criterion for the classification is based on the original systems of Curry and Church, which might be called implicit typing and explicit typing, respectively. This division is the subject of section 2. Section 3 systematically discusses the main ingredients of implicit type systems, and section 4 does the same for explicit type systems. Section 4 concludes with a taxonomy of explicit systems by means of generalised type systems, including the \(lambda\)-cube' introduced in Barendregt [1989]. Since all systems discussed in this paper are ultimately based on the type-free lambda calculus, we conclude this introduction with a short review of that system for reference purposes.
1.1 TYPE-FREE LAMBDA CALCULUS

The aspects of lambda calculus important for functional programming consist of the syntax of terms and the reduction (rewrite) relation on these.

1.1.1. Definition. The sets of (term) variables $V$, of constants $C$ and of lambda terms $\Lambda$ are defined by the following abstract syntax.

$$V = x \mid V'$$

$$C = c \mid C'$$

$$\Lambda = V \mid C \mid \Lambda \mid \lambda V.\Lambda$$

So $V = \{x, x', x'', \ldots\}$ and $C = \{c, c', c'', \ldots\}$.

1.1.2. Conventions.

(i) $x, y, z, \ldots$ range over $V$.

(ii) $a, b, c, \ldots$ range over $C$.

(iii) $M, N, L, \ldots$ range over $\Lambda$.

(iv) $\equiv$ stands for syntactic equality.

(v) $MN_1 \ldots N_k \equiv \ldots((MN_1)N_2)\ldots N_k$, association to the left.

(vi) $\lambda x_1 \ldots x_k. M \equiv \lambda x_1. (\lambda x_2. \ldots(\lambda x_k. (M))..)$, association to the right.

1.1.3. Examples. The following are lambda terms.

(i) $\lambda x. x$.

(ii) $y(\lambda x. x)$.

(iii) $(\lambda x.xx)(\lambda x.xx)$

1.1.4. Definition

(i) $FV(M)$ is the set of free variables of $M$.

(ii) $M[x := N]$ is the result of substituting $N$ for the free occurrences of $x$ in $M$.

1.1.5. Definition (Reduction).

(i) A binary relation $\rightarrow_{\beta}$ (one step reduction) is defined on $\Lambda$ as follows.

$$\lambda x. M \rightarrow_{\beta} M[x := N];$$

$$\begin{align*}
M \rightarrow_{\beta} M' & \quad \iff \quad MN \rightarrow_{\beta} M'N; \\
M \rightarrow_{\beta} M' & \quad \iff \quad NM \rightarrow_{\beta} NM'; \\
\lambda x. M \rightarrow_{\beta} \lambda x. M' & \quad \iff \quad M \rightarrow_{\beta} M'.
\end{align*}$$

(ii) Many step reduction $\rightarrow_{\beta}$ is the reflexive transitive closure of $\rightarrow_{\beta}$.

(iii) Conversion $=_{\beta}$ is the equivalence relation generated by $\lambda \rightarrow_{\beta}$. 

Instead of $\rightarrow_{\beta}$, $\rightarrow_{\beta}$ and $=_{\beta}$ we often write $\rightarrow$, $\rightarrow$ and $=$, respectively.

1.1.6. Examples.

(i) $(\lambda x.xx)(\lambda y.y)z \rightarrow (\lambda y.y)(\lambda y.y)z \rightarrow z.$

(ii) $(\lambda x.y.x) z w \rightarrow z.$

(iii) $(\lambda x.xx)(\lambda y.y)z = (\lambda x.y.x)zw.$

1.1.7. Definition.

(i) $M \in \Lambda$ is called a normal form (nf) if for no $N$ one has $M \rightarrow N$.

(ii) $M$ has a nf $N$ if $M \rightarrow N$ and $N$ is a nf.

(iii) $M$ is strongly normalising, notation $SN(M)$, if for no infinite sequence $M_1, M_2, ...$ one has $M \rightarrow M_1 \rightarrow M_2 \rightarrow ... .$

1.1.8. Examples.

(i) $(\lambda x.xx)y$ has $yy$ as nf.

(ii) $\Omega = (\lambda x.xx)(\lambda x.xx)$ has no nf.

(iii) $(\lambda x.y.x) a \Omega$ has a as nf, but is not strongly normalising since $\Omega \rightarrow \Omega \rightarrow ... .$

1.1.9. Theorem (Church-Rosser property).

(i) If $M \rightarrow M_1$, and $M \rightarrow M_2$ then for some $M_3 \in \Lambda$ one has $M_1 \rightarrow M_3$ and $M_2 \rightarrow M_3$.

(ii) If $M_1 = M_2$, then for some $M_3 \in \Lambda$ one has $M_1 \rightarrow M_3$ and $M_2 \rightarrow M_3$.

1.1.10. Corollary (Unicity of normal forms). A lambda term has at most one nf.

There are certain terms in normal form $^\tau 0^\tau, ^\tau 1^\tau, ...$ (numerals) that represent the elements of $\mathbb{N}$, the set of natural numbers.

1.1.11. Theorem (Lambda definability of computable functions).

(i) Let $f : \mathbb{N} \rightarrow \mathbb{N}$ be a computable function. Then for some $F \in \Lambda$ one has for all $n \in \mathbb{N}$

\[ F \ ^\tau n^\tau \rightarrow ^\tau f(n)^\tau. \]

(ii) More generally, if $f : \mathbb{N}^k \rightarrow \mathbb{N}$ is computable, then for some $F \in \Lambda$ one has for all $n_1, ..., n_k \in \mathbb{N}$

\[ F \ ^\tau n_1^\tau \ ... \ ^\tau n_k^\tau \rightarrow ^\tau f(n_1, ..., n_k)^\tau. \]

This is the basis of evaluation of functional programs. The input and program form together one expression and by the Church-Rosser theorem it does not matter how reductions are done, as long as one cares to find the normal form (if it exists). For this there are several possible normalising strategies, for example leftmost reduction.
One way (but not the only) of obtaining representations of recursive functions is to use the so called fixed point operator \( Y \).

1.1.12. Theorem. Let \( Y \equiv \lambda f. (\lambda x.f(xx))(\lambda x.f(xx)) \). Then \( Y \) produces fixed points, i.e. for every \( F \) one has \( F(YF) = YF \). Turing's fixed point operator \( \Theta \equiv (\lambda ab.b(aab))(\lambda ab.b(aab)) \) even has the property \( \Theta F \rightarrow F(\Theta F) \).

2. IMPLICIT VERSUS EXPLICIT TYPING

There are two ways in which expressions denoting algorithms can be typed: the implicit way, originating with Curry [1934], and the explicit way, originating with Church [1941].

In the systems of implicit typing the expressions are the type-free lambda terms. To each such term a set of possible types is assigned. The number of elements in this set may be zero, one or more. If type \( \sigma \) is assigned to term \( M \), then one writes \( M : \sigma \) (pronounce 'M in \( \sigma \')). An example (to be treated in detail later) is
\[
(\lambda x.x) : (\alpha \rightarrow \alpha),
\]
that is, the identity is of type \( \alpha \rightarrow \alpha \). This means that if \( y : \alpha \), then \( ((\lambda x.x)y) : \alpha \). Also one has \( (\lambda x.x) : ((\alpha \rightarrow \beta) \rightarrow (\alpha \rightarrow \beta)) \). Indeed, if \( f : \alpha \rightarrow \beta \), then \( ((\lambda x.x)f) : (\alpha \rightarrow \beta) \). Therefore one, says that the identity is polymorphic.

In the systems of explicit typing the expressions are annotated versions of lambda terms. Such an expression has a type that usually is uniquely determined by the annotations. An example is
\[
(\lambda x:\alpha.x) : (\alpha \rightarrow \alpha).
\]
One may write \( I_{\sigma} \equiv (\lambda x:\sigma.x) : (\sigma \rightarrow \sigma) \) for the identity on \( \sigma \). In particular \( I_{\alpha \rightarrow \beta} : (\alpha \rightarrow \beta) \rightarrow (\alpha \rightarrow \beta) \).

The components of an algorithm as given by a term usually have a fixed intended meaning. Therefore the explicitly typed terms are rather natural. However, it is often space and time consuming to annotate programs with types. Moreover, the annotation often can be constructed from the type-free expression by automatic means. Therefore the implicit typing paradigm is rather convenient.

Now we will introduce the most basic typed system, the simply typed lambda calculus, both in the style of Curry and that of Church. These systems will be denoted by \( \lambda \rightarrow \text{-Curry} \) and \( \lambda \rightarrow \text{-Church} \).

2.1 THE IMPLICIT VERSION OF \( \lambda \rightarrow \)

Types and terms of \( \lambda \rightarrow \text{-Curry} \).

There are many systems of types. The set of types for \( \lambda \rightarrow \), notation Type \( (\lambda \rightarrow) \), is defined by the following abstract grammar. We write \( T = \text{Type} (\lambda \rightarrow) \).

2.1.1. Definition
\[
\begin{align*}
V &= \alpha | V' & \text{(type variables)} \\
C &= \gamma | C' & \text{(type constants)} \\
T &= V | C | T \rightarrow T & \text{(types)}
\end{align*}
\]
Notice that \( V = \{\alpha, \alpha', \alpha'', \ldots\} \). We will use \( \alpha, \beta, \gamma, \ldots \) to denote arbitrary type variables. Similarly \( C = \{\gamma, \gamma', \gamma'', \ldots\} \). We will use \( \alpha, \beta, \gamma, \ldots \) to denote arbitrary type constants. Elements of \( T \) are \( \alpha, \alpha \to \alpha, \beta \to \alpha \to \alpha \). Here and elsewhere we use association to the right for \( \to \); that is, the last type is really \( \beta \to (\alpha \to \alpha) \). The letters \( \sigma, \tau, \rho, \ldots \) denote arbitrary elements of \( T \).

2.1.2. Definition. (i) A statement is of the form \( M : \sigma \) with \( M \in \Lambda \) and \( \sigma \in T \). In this case \( M \) is called the subject and \( \sigma \) the predicate.

(ii) A basis is a set of statements with as subjects distinct (term) variables. The letters \( \Gamma, \Delta, \ldots \) range over bases.

Some of the type constants are given special names, like \texttt{int}, \texttt{bool}, \texttt{char}. These are used for formulating extensions of \( \lambda \to \) in which certain elements are highlighted. For example term constants \( 0, s \) may be selected and \( \lambda \to \) can be extended with the axioms

\[
\begin{align*}
0 : \texttt{int}, & \quad s : \texttt{int} \to \texttt{int} \\
\end{align*}
\]

Of course everything could be done with free variables. Indeed term variables \( x_0 \) and \( x_s \) and a type variable \( \alpha_{\text{int}} \) can be selected and one can consider as a basis

\[
\begin{align*}
x_0 : \alpha_{\text{int}}, & \quad x_s : \alpha_{\text{int}} \to \alpha_{\text{int}}
\end{align*}
\]

In fact a constant is nothing but a variable that is not and will not be bound.

Assignment rules of \( \lambda \to \) Curry

2.1.3 Definition. A statement \( M : \sigma \) is derivable in \( \lambda \to \) form a basis \( \Gamma \), notation \( \Gamma \vdash \lambda \to M : \sigma \) or simply \( \Gamma \vdash M : \sigma \) if there is no danger of confusion, if \( \Gamma \vdash M : \sigma \) can be produced by the following assignment rules.

(Start) \( \Gamma \vdash x : \sigma \), if \( x : \sigma \) is in \( \Gamma \);

\[
\begin{align*}
(\to E) \quad \Gamma \vdash M : (\sigma \to \tau), & \quad \Gamma \vdash N : \sigma, \\
& \quad \Gamma \vdash (MN) : \tau \\
\end{align*}
\]

\[
\begin{align*}
(\to I) \quad & \quad \Gamma, x : \sigma \vdash M : \tau, \\
& \quad \Gamma \vdash (\lambda x.M) : (\sigma \to \tau)
\end{align*}
\]

Here \( \Gamma, x : \sigma \) stands for \( \Gamma \cup \{x : \sigma\} \). If \( \Gamma = \emptyset \), then \( \Gamma \vdash M : \sigma \) is written as \( \vdash M : \sigma \). Pronounce \( \vdash \) as yields. \( \Gamma \vdash M : \sigma \) means that \( \Gamma \vdash M : \sigma \) does not hold. The rule \( \to E \) stands for \( \to \)-elimination; \( \to I \) for \( \to \)-introduction.

2.1.4. Examples.

(i) The following derivation shows that \( \vdash \lambda \to (\lambda xy.x) : (\sigma \to \tau \to \sigma) \). The derivation is written in a version of natural deduction, due to N.G. de Bruijn, in which the scope of assumptions is made explicit.
Properties of $\lambda \rightarrow$-Curry.

There are several valid properties of $\lambda \rightarrow$ in which reduction and type assignment play a role. Since several (but not all) of these are valid also for other systems, we will indicate them by an acronym for quick reference. Not all versions of some property are exactly the same though and the precise formulation is given in case the statement differs from the standard meaning.

2.1.5. Definition. The following acronyms are used for properties of type systems.

(i) CR (Church-Rosser property).
This refers to the set of terms and reduction and conversion. The formulation is in 1.1.9.

(ii) SR (Subject reduction property). This states the following. Let $M \rightarrow M'$. Then
\[ \Gamma \vdash M : \sigma \Rightarrow \Gamma \vdash M' : \sigma. \]

(iii) SN (Strong normalisation property). This is
\[ \Gamma \vdash M : \sigma \Rightarrow \text{SN} (M). \]

(iv) UT (Unicity of types). This is
\[ \Gamma \vdash M : \sigma \& \Gamma \vdash M : \sigma' \Rightarrow \sigma = \sigma'. \]

(v) $\Gamma \vdash M : \sigma$ is decidable. This states that given, $\Gamma, M, \sigma$ it is decidable whether $\Gamma \vdash M : \sigma$.

(vi) $\Gamma \vdash M : ?$ is computable. This states that given $\Gamma, M$ it can be decided whether there is a $\sigma$ such that $\Gamma \vdash M : \sigma$ and moreover one such $\sigma$ can be computed from $\Gamma, M$.

Property 2.1.5 (iii) implies that not every computable function is lambda definable, see Barendregt [1990], theorem 4.2.15.

2.1.6. Theorem. For $\lambda \rightarrow$-Curry the following properties hold.

(i) CR, for $\Lambda$ and $\beta$-reduction/-conversion.

(ii) SR.

(iii) SN.

(iv) $\Gamma \vdash M : \sigma$ is decidable.

(v) $\Gamma \vdash M : ?$ is computable.
2.1.7. Remarks. (i) The converse of SR does not hold for \( \lambda \rightarrow \). Let \( S = \lambda x y z . x z ( y z ) \) and \( K = \lambda p q . p \). Then \( SK \rightarrow \lambda x y . y \) and \( \lambda ( x y . y ) : ( \sigma \rightarrow \tau \rightarrow \tau ) \) but \( \not \exists \ SK : ( \sigma \rightarrow \tau \rightarrow \tau ) \).

(ii) \( M \) is called typable if \( \Gamma \vdash M : \sigma \) for some \( \Gamma \) and \( \sigma \). SN states that if \( M \) is typable, then \( M \) is strongly normalising. The converse is not true. E.g. \( \lambda x . x x \) is not typable.

(iii) Computability of \( \Gamma \vdash M : ? \) has been established independently by Hindley [1969] for a combinator version of \( \lambda \rightarrow \) and by Milner [1978] for the closely related programming language ML. The ML-algorithm analyses the term \( M \) and generates a set \( E \) of equations between types in such a way that \( M \) is typable iff \( E \) has a solution. Moreover, the most general type of \( M \) corresponds to the most general solution of \( E \). The latter solution can be found by applying a unification algorithm to \( E \). A clear description of such an algorithm has been given by Wand [1987].

**Pragmatics of \( \lambda \rightarrow \cdot \) Curry**

There exist various programming languages with type systems closely resembling \( \lambda \rightarrow \cdot \)Curry, such as ML (Harper [1986]), Hope (Burstall [1980]) and Miranda (Turner [1985]). The ML type system, invented by Milner [1978] independently from Hindley’s work, has been discussed extensively in the literature (Damas [1982], Mycroft [1984], Kfoury [1988, 1989]). The system is based on an extension of \( \lambda \rightarrow \cdot \)Curry with a declaration mechanism of the form \( \text{let } x = M \text{ in } N \), which allows a form of polymorphism in the sense that different occurrences of \( x \) in \( N \) may have different types which are instances of a type scheme for \( x \) and \( M \). In this section we consider the basic system introduced by Milner and some of its extensions. All systems are based on the following sets of terms, types and type schemes.

\[
\begin{align*}
\Lambda & = V \mid C \mid \lambda \cdot V \cdot \Lambda \mid \text{let } V = \Lambda \mid \text{fix } V \cdot \Lambda \\
T & = V \mid C \mid T \rightarrow T \\
\Sigma & = T \mid \forall V . \Sigma
\end{align*}
\]

It follows that universal quantifiers may only occur at the top level of type schemes. In the remainder of this section we shall use metavariables \( \tau \) and \( \sigma \) to range over types and type schemes, respectively. It will be necessary to consider ‘generic instances’ of type schemes. Let \( \sigma = \forall \alpha_1 \ldots \alpha_m . \tau \) and \( \sigma' = \forall \beta_1 \ldots \beta_n . \tau' \). Then \( \sigma' \) is a generic instance of \( \sigma \), written \( \sigma \leq \sigma' \), iff there is a substitutor \( S \) acting only on \( \{ \alpha_1 \ldots \alpha_m \} \) such that \( \tau' = S(\tau) \) and no \( \beta_i \) is free in \( \sigma \). If we consider \( \sigma \leq \sigma' \) iff \( \sigma \leq \sigma ' \leq \sigma \), then \( (\Sigma, \leq) \) is a partial order with least element \( \forall \alpha . \alpha \). The following graph, taken from Mycroft [1984], illustrates the order \( \leq \).
The first type assignment system we consider for this language is the one of Milner [1978] in the form of Damas [1982]. Once more we note that \( \tau \) ranges over types and \( \sigma \) over type schemes.

\[
\begin{align*}
\text{(var)} & \quad \Gamma \vdash x : \sigma, \quad \text{if} \ (x : \sigma) \in \Gamma; \\
\text{(inst)} & \quad \frac{\Gamma \vdash M : \sigma}{\Gamma \vdash M : \sigma'} \quad \text{if} \ \sigma \leq \sigma'; \\
\text{(gen)} & \quad \frac{\Gamma \vdash M : \sigma}{\Gamma \vdash M : \forall \alpha. \sigma'} \quad \text{if} \ \alpha \in \text{FV}(\Gamma); \\
\text{(m-app)} & \quad \frac{\Gamma \vdash M : \tau_1 \to \tau_2, \ \Gamma \vdash N : \tau_1}{\Gamma \vdash MN : \tau_2}; \\
\text{(m-abs)} & \quad \frac{\Gamma, x: \tau_1 \vdash M : \tau_2}{\Gamma \vdash \lambda x. M : \tau_1 \to \tau_2}; \\
\text{(m-fix)} & \quad \frac{\Gamma, x: \tau_1 \vdash M : \tau}{\Gamma \vdash \text{fix} x. M : \tau}; \\
\text{(p-let)} & \quad \frac{\Gamma, x: \sigma \vdash N : \tau, \ \Gamma \vdash M : \sigma}{\Gamma \vdash \text{let} x=M \text{ in } N : \tau}.
\end{align*}
\]

The intended meaning of \( \text{fix} x. M \) is in terms of the type-free lambda calculus \( \Theta(\lambda x. M) \). The meaning of \( \text{let} x=M \text{ in } N \) is \( N[x:=M] \). For practical purposes this basic language can be extended with other language constructs defined in terms of the given ones. For example, the construct

\[\text{letrec } x = M \text{ in } N\]

can be defined as

\[\text{let } x = \text{fix} x. M \text{ in } N.\]

Consider as an example the following declaration (taken from Milner [1978])

\[\text{letrec map } = \lambda f, m. \text{if} \ (\text{null } m) \ (\text{nil}) \ (\text{cons} (f \ (\text{hd } m)) (\text{map} f \ (\text{tl } m)))\]

which is equivalent to
let map =
    fix map'.λf,m. if (null m) nil (cons (f (hd m)) (map' f (tl m)))

Assuming the following basis

null : ∀α.(list α→bool)
nil : ∀α.(list α)
cons : ∀α.(α→list α→list α)
hd : ∀α.(list α→α)
tl : ∀α.(listα→list α)
if : ∀α.(bool→α→α→α)

one can deduce

map : ∀α ∀β.((α→β)→(list α→list β)).

To every occurrence of the variable map within the scope of the declaration must be assigned a type which is a generic instance of this type scheme. E.g., if we assume a type xxx and variables

x : list xxx
f : xxx → int
odd : int → bool

then in the expression

map odd (map f x)

the inner and outer occurrence of map will have types

(xxx→int) →(list xxx → list int)
(int → bool) →(list int → list bool)

respectively.

The first extension to the system above has been suggested by Mycroft [1984] in order to remedy some unexpected consequences of the basic system. E.g. if the definition of map as given above is followed by a definition

let oddlist = λl.map odd l

then the ML system will derive the types

map : ∀α ∀β. (((α→β) → (list α) → (list β))
oddlist : (list int) → (list bool)

whereas, if they are defined simultaneously by

letrec map = λf. m ...
and oddlist = λl. map odd l

the system will derive
map : (int → bool) → (list int) → (list bool)
oddlist : (list int) → (list bool).

This phenomenon is due to the fact that a simultaneous recursive definition

```
letrec f1 = \x1.M1
   and f2 = \x2.M2
```

is equivalent to

```
let <f1, f2> = fix <f1, f2>.<M1,M2>
```

and according to the type assignment rule (m-fix) bound variables of a fix-expression should have types rather than type schemes. In Mycroft [1984] and Kfoury [1988] it has been suggested to replace rule (m-fix) by

```
\frac{\Gamma, x:\sigma \vdash M : \sigma}{\Gamma \vdash fix x . M : \sigma}
```

The resulting system is sometimes referred to as the Milner-Mycroft system. Mycroft could not prove the decidability of type derivation for this system. In Kfoury [1988] a proof is given, but it does not result in a practical algorithm.

A second extension to the basic system has been inspired by another problem, mentioned in Milner [1978] and Kfoury [1989]. Consider a declaration of the form

```
let m = \lambda f. \lambda x. \lambda y. <f x, f y>.
```

One would expect that application of m to arguments

```
(\lambda x.x) : \forall \alpha. \alpha \to \alpha
M_1 : \tau_1
M_2 : \tau_2
```

results in

```
<M_1, M_2> : \tau_1 \times \tau_2
```

but in ML the term

```
let m = \lambda f. \lambda x. \lambda y. <f x, f y> in m (\lambda x.x) M_1 M_2
```

cannot be typed, because according to rule (m-abs) all occurrences of f should have the same type. In Kfoury [1989] it is proposed to replace (m-abs) and (m-app) by

```
\frac{\Gamma, x:\sigma \vdash M : \tau}{\Gamma \vdash \lambda x.M : \sigma \to \tau}
```

```
\frac{\Gamma \vdash M : \sigma \to \tau \quad \Gamma \vdash N : \sigma}{\Gamma \vdash MN : \tau}
```

thus allowing functions to accept polymorphic arguments. For the resulting system the computability of type derivation is open. In fact that system comes close to the system \lambda2-Curry, which is the subject of section 3.1.
2.2. THE EXPLICIT VERSION OF $\lambda \rightarrow$

Unless stated otherwise, in this subsection $\lambda \rightarrow$ stands for the explicit (Church) version of the simply typed lambda calculus.

Types and terms of $\lambda \rightarrow$ - Church

The set of types for this version of $\lambda \rightarrow$, notation $T = \text{Type} (\lambda \rightarrow)$, is the same as for the implicit version of $\lambda \rightarrow$, viz.

$$T = \forall \exists \mathbb{C} \mathbb{T} \rightarrow T.$$

2.2.1 Definition. The set of pseudoterms of $\lambda \rightarrow$, notation $\Lambda_T$, is defined as follows.

$$\Lambda_T = \forall \exists \mathbb{C} \mathbb{T} \Lambda_T \rightarrow \forall \exists \mathbb{V} : \forall \exists \mathbb{T} \Lambda_T.$$

For example $\lambda x : \alpha . x$ and $y (\lambda x : \alpha \rightarrow \alpha . xy)$ are in $\Lambda_T$. The first one will turn out to have a type, the second one not.

Assignment rules of $\lambda \rightarrow$ - Church.

2.2.2 Definition. $\Gamma \vdash_{\lambda \rightarrow} M : \sigma$ is defined by the following axiom and rules.

\[
\begin{align*}
\text{(start)} & \quad \Gamma \vdash x : \sigma, \text{ if } (x : \sigma) \in \Gamma; \\
\text{($\rightarrow$E)} & \quad \frac{\Gamma \vdash M : (\sigma \rightarrow \tau) \quad \Gamma \vdash N : \sigma} {\Gamma \vdash (MN) : \tau} \\
\text{($\rightarrow$I)} & \quad \frac{\Gamma, x : \sigma \vdash M : \tau} {\Gamma \vdash (\lambda x : \sigma . M) : \sigma \rightarrow \tau} 
\end{align*}
\]

2.2.3 Examples.

\begin{enumerate}
  \item \(\vdash_{\lambda \rightarrow} (\lambda x : \sigma . x) : (\sigma \rightarrow \tau \rightarrow \sigma).\)
  \item \(\vdash_{\lambda \rightarrow} (\lambda x : \sigma . (\lambda y : \tau . y)) : (\sigma \rightarrow \tau \rightarrow \tau).\)
  \item \(\vdash_{\lambda \rightarrow} (\lambda x : \sigma . x) : (\sigma \rightarrow \sigma).\)
  \item \(y : \sigma \vdash_{\lambda \rightarrow} ((\lambda x : \sigma . x) y) : \sigma.\)
\end{enumerate}

2.2.4 Definition. A pseudoterm $M$ is called legal if for some $\Gamma$ and $\sigma$ one has $\Gamma \vdash_{\lambda \rightarrow} M : \sigma$.

For example $(\lambda x : \sigma . x)$ and $(\lambda x : \sigma . x) y$ are legal, but $(\lambda x : \alpha . xx)$ is not.

The notations of $\beta$-reduction and $\beta$-conversion are extended to pseudoterms. First of all the notion of substitution is extended to $\Lambda_T$ in the obvious way. Then the contraction rule on pseudoterms

\[(\lambda x : \sigma . M) N \rightarrow M [x := N] \quad (\beta)\]
generates $\beta$-reduction, denoted again by $\rightarrow$, and $\beta$-conversion, denoted by $\Rightarrow$. Note that in ($\beta$) the term $N$ does not need to match the type $\sigma$.

Properties of $\lambda \rightarrow$-Church

2.2.5 Theorem. The following properties hold for $\lambda \rightarrow$.

(i) CR, for the extended notion of reduction and conversion on $\lambda T$.

(ii) SR.

(iii) SN.

(iv) $\Gamma \vdash \lambda \rightarrow M: \sigma$? is decidable.

(v) $\Gamma \vdash \lambda \rightarrow M:?$ is computable.

Relation between $\lambda \rightarrow$-Curry and $\lambda \rightarrow$-Church

There is a relation between the implicit and explicit version of $\lambda \rightarrow$. In order to express this we need a map from pseudoterms to type-free terms.

2.2.6. Definition. A map $\downarrow: \lambda T \rightarrow \Lambda$ is defined by erasing all type annotations.

\[\downarrow x = x, \downarrow c = c,\]

\[\downarrow MN = \downarrow M \downarrow N,\]

\[\downarrow \lambda x: \sigma.M = \lambda x.\downarrow M.\]

2.2.7. Proposition.

(i) $\Gamma \vdash \lambda \rightarrow$-Church $M: \sigma \Rightarrow \Gamma \vdash \lambda \rightarrow$-Curry $\downarrow M : \sigma$.

(ii) $\Gamma \vdash \lambda \rightarrow$-Curry $M: \sigma \Rightarrow \exists M' [ \downarrow M' \equiv M \& \Gamma \vdash \lambda \rightarrow$-Church $M': \sigma]$.

Pragmatics of $\lambda \rightarrow$-Church

Edinburgh LCF, a Logic of Computable Functions, see Gordon et al.[1979], is essentially $\lambda \rightarrow$-Church, extended with a fixed point combinator.

3. IMPLICIT TYPING

In this section three systems of typed lambda calculus à la Curry will be introduced. These systems are all extensions of the implicit version of $\lambda \rightarrow$. The three systems are the polymorphic lambda calculus $\lambda 2$, the system with recursive types $\lambda \mu$ and the system with intersection types $\lambda \cap$. The system $\lambda 2$ will also be encountered in section 4.1 in an explicit version. A system à la Curry that includes all of $\lambda 2$, $\lambda \mu$ and $\lambda \cap$ as subsystems has been described in MacQueen, Plotkin and Sethi [1986].

3.1. POLYMORPHISM

In $\lambda \rightarrow$-Curry one has that $\vdash \lambda \rightarrow (\lambda x.x) : (\sigma \rightarrow \sigma)$ for every type $\sigma$. The fact that $\lambda x.x$ has several types is called polymorphism. This can be made explicit by allowing as type $\forall \alpha. \alpha \rightarrow \alpha$ and as statement $(\lambda x.x)$:
\(\forall \alpha.\alpha \rightarrow \alpha\). The system \(\lambda 2\), introduced by Girard [1972] and Reynolds [1974] in the Church version, will be able to express this. In this subsection we will introduce \(\lambda 2\)-Curry.

**Types and terms of \(\lambda 2\)-Curry**

The terms of \(\lambda 2\) are those of \(\lambda \to\), see definition 1.1.1.

3.1.1 Definition. The types of \(\lambda 2\), notation \(T = \text{Type} (\lambda 2)\), are defined by the following abstract grammar.

\[
T = V \mid C \mid T \rightarrow T \mid \forall V.T
\]

Notation. (i) \(\forall \alpha_1 \ldots \alpha_n. \sigma = \forall \alpha_1.(\forall \alpha_2. \ldots (\forall \alpha_n.(\sigma))\ldots)\).

(ii) \(\bot = \forall \alpha.\alpha\).

Examples of types
- \(\forall \alpha.\alpha \to \alpha\);
- \(\forall \alpha\beta.\alpha \to \beta\);
- \(\forall \alpha.\bot \to \beta\).

**Assignment rules of \(\lambda 2\)-Curry**

3.1.2 Definition.

\[
\begin{align*}
\text{(Start)} & \quad \Gamma \vdash x : \sigma, \quad \text{for } (x: \sigma) \in \Gamma; \\
\text{(-E)} & \quad \frac{\Gamma \vdash M : \sigma \to \tau, \Gamma \vdash N : \sigma}{\Gamma \vdash MN : \tau}; \\
\text{(-I)} & \quad \frac{\Gamma, x : \sigma \vdash M : \tau}{\Gamma \vdash (\lambda x.M) : \sigma \to \tau}; \\
\text{(-E)} & \quad \frac{\Gamma \vdash M : \forall \alpha.\sigma}{\Gamma \vdash M : \sigma[\alpha := \tau]}; \\
\text{(VI)} & \quad \frac{\Gamma \vdash M : \sigma}{\Gamma \vdash M : \forall \alpha.\sigma}, \text{if } \alpha \notin \text{FV}(\Gamma).
\end{align*}
\]

3.1.3 Examples

\[
\begin{align*}
\vdash \lambda 2 (\lambda x.x) : (\forall \alpha.\alpha \to \alpha) \\
\vdash \lambda 2 (\lambda xy.x) : (\forall \beta.\alpha \to \beta \to \alpha) \\
\vdash \lambda 2 (\lambda x.xx) : (\forall \beta.\bot \to \beta)
\end{align*}
\]

This last fact has the following derivation
Properties of $\lambda^2$-Curry

3.1.4. Theorem. The following properties hold for $\lambda^2$.

(i) $CR$.

(ii) $SR$.

(iii) $SN$.

It is not known whether the properties

$\Gamma \vdash M : \sigma''$ is decidable

$\Gamma \vdash M : ?$ is computable

are valid. (R. Milner calls them 'embarrassing open problems'.)

3.2. RECURSIVE TYPES

If we had a type $\sigma$ such that $\sigma = \sigma \to \sigma$, and moreover an $x : \sigma$, then $x$ can be applied to itself to obtain $xx : \sigma$. Therefore for such a $\sigma$ one has $(\lambda x.x) : (\sigma \to \sigma)$ and hence $(\lambda x.x) : \sigma$. Solutions of the equation $\sigma = \sigma \to \sigma$ are obtained axiomatically by writing $\sigma = \mu \alpha. \alpha \to \alpha$ which has to be interpreted like 'some solution of $\alpha = \alpha \to \alpha$'.

Types and terms of $\lambda\mu$-Curry

The terms of $\lambda\mu$ are those of $\lambda \to$, see definition 1.1.1.

3.2.1. Definition. The set of types of $\lambda\mu$, notation $T = \text{Type}(\lambda\mu)$, is defined as follows.

$$T = V \mid C \mid T \rightarrow T \mid \mu V. T$$

Notation. $\mu \alpha_1 \ldots \alpha_n. \sigma = \mu \alpha_1. (\mu \alpha_2. \ldots (\mu \alpha_n. (\sigma)) \ldots)$.

Assignment rules of $\lambda\mu$-Curry

In order to state that the $\mu$ types satisfy what they are intended to do, some congruence relation $=$ on types is defined such that for example $\sigma = (\sigma \to \sigma)$ for $\sigma = \mu \alpha. \alpha \to \alpha$. This relation $=$ is defined using trees corresponding to types. The definition of the trees is somewhat informal, but clear enough when seeing the examples.
3.2.2. Definition. Let \( \sigma \in \text{Type}(\lambda \mu) \). The tree corresponding to \( \sigma \), notation \( T(\sigma) \), is defined as follows.

\[
T(\delta) = \begin{cases} \delta, & \text{if } \delta \text{ is a type variable or constant;} \\
T(O), & \text{else}
\end{cases}
\]

\[
T(\sigma \rightarrow \tau) = \begin{array}{c}
\sigma \\
T(\sigma)
\end{array}
\begin{array}{c}
\tau \\
T(\tau)
\end{array};
\]

\[
T(\mu \alpha . \sigma) = T(\sigma[\alpha := \mu \alpha . \sigma]) \text{ if defined; else }...
\]

Examples.

\[
T(\alpha \rightarrow \beta \rightarrow \alpha) = \begin{array}{c}
\alpha \\
\beta
\end{array}
\begin{array}{c}
\alpha
\end{array};
\]

3.2.3. Definition. Let \( \sigma, \tau \in \text{Type}(\lambda \mu) \). Then \( \sigma \) and \( \tau \) are equivalent, notation \( \sigma = \tau \), if \( T(\sigma) = T(\tau) \).

Examples. If \( \sigma = \mu \alpha . \alpha \rightarrow \alpha \), then \( \sigma = \tau \rightarrow \sigma \). This could have been derived from the axiom

\[
\mu \alpha . \sigma = \sigma[\alpha := \mu \alpha . \sigma].
\]

However, the following equation cannot be obtained from this axiom

\[
\mu \alpha . \beta \rightarrow \alpha = \mu \alpha . \beta \rightarrow \beta \rightarrow \alpha.
\]

Therefore the definition of \( = \) is given using trees.
3.2.4. Definition.

(Start) \[ \Gamma \vdash x : \sigma \quad \text{for} \ (x : \sigma) \in \Gamma \]

\[ \vdash \frac{\Gamma \vdash M : \sigma \rightarrow \tau \quad \Gamma \vdash N : \sigma}{\Gamma \vdash MN : \tau} \quad (\rightarrow E) \]

\[ \vdash \frac{\Gamma, x : \sigma \vdash M : \tau}{\Gamma \vdash (\lambda x.M) : \sigma \rightarrow \tau} \quad (\rightarrow I) \]

\[ \begin{align*}
(\approx) & \quad \frac{\Gamma \vdash M : \sigma}{\Gamma \vdash M : \tau} \\
& \quad \text{if } \sigma = \tau.
\end{align*} \]

3.2.5. Examples.

(i) Morris [1968]. Let \[ Y \equiv \lambda f. (\lambda x.f(xx))(\lambda x.f(xx)) \]. Then \[ \vdash \mu Y : (\sigma \rightarrow \sigma) \rightarrow \sigma \] for all \( \sigma \). Indeed, define \( \tau = \mu \alpha. \alpha \rightarrow \sigma \), then \( \tau = \tau \rightarrow \sigma \) and we can construct the following derivation.

\[
\begin{array}{c}
f : \sigma \rightarrow \sigma \\
\hline
x : \tau \\
\hline
f (xx) : \sigma \\
(\lambda x.f(xx)) : \tau \rightarrow \sigma \\
(\lambda x.f(xx)) : \tau \\
(\lambda x.f(xx))(\lambda x.f(xx)) : \sigma \\
(\lambda f(\lambda x.f(xx))(\lambda x.f(xx)) : (\sigma \rightarrow \sigma) \rightarrow \sigma \\
Y : (\sigma \rightarrow \sigma) \rightarrow \sigma
\end{array}
\]

(ii) Similarly, one shows \[ \vdash \mu (\lambda x.xx) (\lambda x.xx) : \sigma \].

Properties of \( \lambda \mu \)-Curry

3.2.6 Theorem. The following properties hold for \( \lambda \mu \).

(i) CR.

(ii) SR.

(iii) SN fails, \( (Y \text{ can be typed}) \).

(iv) \[ \Gamma \vdash M : ? \text{ is decidable (Cardone and Coppo [1990])} \].

(v) \[ \Gamma \vdash M : ? \text{ is computable (trivial, using } \mu \alpha. \alpha \rightarrow \alpha \).} \]

Mendler [1987] has shown that there exists a restricted version of \( \lambda \mu \)-Church in which all typable terms are strongly normalizing, the restriction being that in \( \mu \alpha. \sigma \) the variable \( \alpha \) may not occur at negative positions in \( \sigma \). This result probably holds for \( \lambda \mu \)-Curry as well.
Pragmatics of $\lambda\mu$-Curry

Recursive types occur in many programming languages, but usually in combination with simple type constructors like $+$ (disjoint sum) and $\times$ (cartesian product) only. For example, given a unit type $1$ and a type $\tau$, one can form the type of lists over $\tau$ as

$$\mu\alpha.1 + \tau \times \alpha$$

and the type of binary trees over $\tau$ as

$$\mu\alpha.1 + \tau \times \tau \times \alpha.$$  

Few programming languages allow combinations of $\mu$ in full generality. One of the first languages to do so was ALGOL 68 (Van Wijngaarden [1969]), where e.g. the 'mode declaration'

$$\text{mode } m = \text{proc } (m) m$$

corresponds to $\mu\alpha.\alpha \rightarrow \alpha$. An illuminating discussion on ALGOL 68 mode declarations and their relation to domain equations is presented in Lehmann [1977].

3.3. INTERSECTION TYPES

The system of lambda calculus with intersection types, notation $\lambda\cap$, is taken from Barendregt, Coppo and Dezani [1983], which paper is based on earlier work of Coppo, Dezani, Sallé and Venneri. If in $\lambda\cap$ one has $M : \sigma$ and $M : \tau$, then one has $M : (\sigma \cap \tau)$. Moreover there is a universal type $\omega$ such that $M : \omega$ for all terms $M$. The operation $\cap$ induces a pre-ordering on types in which $\omega$ is the largest element.

Types and terms of $\lambda\cap$

The terms of $\lambda\cap$ are those of $\lambda\rightarrow$, see definition 1.1.1.

3.3.1. Definition. The set of types of $\lambda\cap$, notation $T = \text{Type}(\lambda\cap)$, is defined as follows

$$T = V \mid C \mid T \rightarrow T \mid T \cap T.$$  

One of the constants of $C$ is selected and is called $\omega$.

Assignment rules of $\lambda\cap$-Curry

3.3.2. Definition (i) On $T$ a relation $\leq$ is defined as follows

$$\sigma \leq \sigma;$$
$$\sigma \leq \omega;$$
$$\sigma \cap \tau \leq \sigma;$$
$$\sigma \cap \tau \leq \tau;$$

$$\sigma \leq \tau, \tau \leq \rho;$$
$$\sigma \leq \tau, \sigma \leq \rho;$$

$$\sigma \leq \rho;$$

$$\sigma \leq \tau \cap \rho;$$

$$(\sigma \rightarrow \rho) \cap (\sigma \rightarrow \tau) \leq \sigma \rightarrow (\rho \cap \tau);$$
\[
\frac{\sigma \leq \sigma', \sigma \leq \tau'}{(\sigma' \to \tau) \leq (\sigma \to \tau')}
\]

(ii) \(\sigma \sim \tau \iff \sigma \leq \tau \) and \(\tau \leq \sigma\).

For example, one has \(\bullet \sim (\bullet \to \bullet)\) and \(((\sigma \cap \sigma' \to \tau) \sim ((\sigma \to \tau) \cap (\sigma' \to \tau))\). We let \(\cap\) bind stronger than \(\to\), so one can write \(\sigma \cap \sigma' \to \tau\) for \((\sigma \cap \sigma') \to \tau\).

3.3.3. Definition.

(Start) \(\Gamma \vdash x : \sigma\), for \((x:\sigma) \in \Gamma\);
(top) \(\Gamma \vdash M : \bullet\);

\[\frac{\Gamma \vdash M : (\sigma \to \tau) \quad \Gamma \vdash N : \sigma}{\Gamma \vdash MN : \tau};\]

\[\frac{\Gamma, x:\sigma \vdash M : \tau}{\Gamma \vdash \lambda x.M : \sigma \to \tau};\]

\[\frac{\Gamma \vdash M : (\sigma \cap \tau)}{\Gamma \vdash M : \sigma, \Gamma \vdash M : \tau};\]

\[\frac{\Gamma \vdash M : \sigma \quad \Gamma \vdash M : \tau}{\Gamma \vdash M : \sigma \cap \tau};\]

(sub) \(\frac{\Gamma \vdash M : \sigma \quad \sigma \leq \tau}{\Gamma \vdash M : \tau}\).

3.3.4. Examples.

(i) \(\vdash \lambda x. (\lambda x.xx) : (\sigma \cap (\sigma \to \tau) \to \tau)\);

(ii) \(\vdash \lambda x. (\lambda x.xx) : \bullet\);

(iii) \(\vdash \lambda x. (\lambda yz.xz(yz))(\lambda xy.x) : (\alpha \to \beta \to \beta)\).

In Van Bakel [1990] it is remarked that although the term in (iii) has a type in \(\lambda \to\), it does not have the type \(\alpha \to \beta \to \beta\) in that system.

Properties of \(\lambda \cap\) Curry

The properties valid for \(\lambda \cap\) are somewhat different from those for the other systems of implicitly typed lambda calculus.

3.3.5. Theorem. For \(\lambda \cap\) the following properties hold.

(i) CR.

(ii) SR.

The stronger notion of Subject Conversion also holds, i.e. if \(M =_\beta M'\) then

\[\Gamma \vdash \lambda \cap M : \sigma \iff \Gamma \vdash \lambda \cap M' : \sigma\]
(iii) SN fails, because every term has type $\emptyset$.
(iv) $\Gamma \vdash M : \sigma ?$ is undecidable.
(v) $\Gamma \vdash M : ?$ holds trivially, because every term has type $\emptyset$.

3.3.6. Remark (i) For the system $\lambda \cap$, obtained form $\lambda \cap$ by omitting rule (top), one has the following result of Van Bakel [1990]

$$SN(M) \iff \exists \Gamma \exists \sigma [\Gamma \vdash \lambda \cap M : \sigma]$$

(ii) $M$ has normal form $\iff \exists \Gamma \exists \sigma [\Gamma \vdash M : \sigma$ and $\emptyset$ does not occur in $\sigma],$

see Barendregt et al. [1983].

Pragmatics of $\lambda \cap$

In $\lambda \cap$ intersection types are used for objects that have various types which are not structurally related. The same phenomenon occurs in many programming languages, where it is called 'overloading'. A well-known example is the use of the symbol $+$ to denote both integer addition, real addition and string concatenation. In the intersection type discipline such a symbol can be given the type $(\text{int} \rightarrow \text{int}) \cap (\text{real} \rightarrow \text{real}) \cap (\text{string} \rightarrow \text{string})$.

Recently new uses of intersection types have been suggested by Reynolds [1989] and Tennent [1989] in connection with ALGOL-like languages. The imperative features of such languages are accommodated by the introduction of so-called phrase types, such as

$$\exp [\tau]$$ for constructs producing a value of type $\tau$

$$\acc [\tau]$$ for constructs accepting a value of type $\tau$, such as the updating component of variables or result parameters of procedures. In denotational semantics these constructors are sometimes called 'l-values'.

$$\var [\tau]$$ for variables of type $\tau$.

For example, in an assignment $x := 3$, the left-hand side and right-hand side have phrase types

$$\acc [\text{int}]$$ and $$\exp [\text{int}]$$, respectively.

Because in ALGOL-like languages a variables of type $\tau$ can both accept and produce a value of type $\tau$, we need the coercions $\var [\tau] \leq \acc [\tau]$ and $\var [\tau] \leq \exp [\tau]$. Using intersection types this can be achieved by defining

$$\var [\tau] = \acc [\tau] \cap \exp [\tau].$$

Another phenomenon occurring in ALGOL-like languages is interference, e.g. when one command assigns to a variable that is evaluated or assigned to by another command. In some cases this interference is undesirable, but in other cases it is very useful or even essential. What is needed are some syntactic constraints to control interference. It is possible to define these constraints using a variant of intersection types. For more details we refer to Reynolds [1989].
4. EXPLICIT TYPING

In this section several extensions of \( \lambda \rightarrow \)-Church will be considered. Three important extensions are \( \lambda 2 \)-Church (second order lambda calculus), the system \( \lambda \omega \) (weakly higher order lambda calculus) and the system \( \lambda P \) (lambda calculus with dependent types). The intuition behind these extensions is the following. Types represent sets (spaces) of functions. Terms denote algorithms representing elements of these function spaces. Now there are four basic dependencies.

- elements depend on elements;
- elements depend on types;
- types depend on types;
- types depend on elements.

These four dependencies will be explained as the main features of respectively the systems \( \lambda \rightarrow, \lambda 2, \lambda \omega \) and \( \lambda P \).

Elements depending on elements are ubiquitous. A function \( f \) of two arguments on a set \( A \) may be used to form \( f(x) \) for \( x \) in \( A \). This \( f(x) \) is an element depending on the element \( x \). The mechanism of abstraction makes this dependency functional. One can form the function \( g = \lambda x : A. f(x) \). This formation of functions is the main feature of all versions of the lambda calculus, in particular of \( \lambda \rightarrow \). The other kind of dependencies will be described in subsections 4.1, 4.2 and 4.3 respectively. Subsection 4.4 gives a uniform treatment of the explicitly typed systems.

4.1 ELEMENTS DEPENDING ON TYPES

In \( \lambda \rightarrow \)-Church one has

\[
\vdash_{\lambda \rightarrow} (\lambda x: \alpha. x) : (\alpha \rightarrow \alpha).
\]

(1)

If one writes \( I_\alpha = (\lambda x: \sigma. x) \), then \( I_\alpha \) is an element that depends on the type \( \sigma \). The system \( \lambda 2 \)-Church makes this depending functional by deriving from (1)

\[
\vdash_{\lambda 2} (\lambda \alpha \lambda x : \alpha. x) : (\forall \alpha. (\alpha \rightarrow \alpha)).
\]

Write \( I_{\text{poly}} = \Lambda \alpha. I_\alpha \). In order to obtain \( I_\sigma \) uniformly in \( \sigma \) from \( I_{\text{poly}} \), a new reduction rule is introduced

\[
I_{\text{poly}} \sigma = (\lambda \alpha. I_\alpha) \sigma \rightarrow I_\sigma.
\]

(\( \beta_2 \))

In particular this implies that terms may be applied to types. In subsection 4.4 it will be seen that (\( \beta_2 \)) can be considered as a particular case of ordinary \( \beta \)-reduction.

Types and terms of \( \lambda 2 \)-Church.

4.1.1. Definition. (i) The set of types for \( \lambda 2 \)-Church, notation \( T = \text{Type}(\lambda 2) \), is the same as for the Curry version

\[
T = V \cup C \cup T \rightarrow T \cup \forall VT.
\]

(ii) The set of pseudoterms for \( \lambda 2 \)-Church, notation \( \Lambda T = \text{Term}(\lambda 2) \) is defined as follows.

\[
\Lambda T = V \cup C \cup \Lambda T \Lambda T \cup \Lambda T T \cup \lambda V : T. \Lambda T \cup \lambda V. \Lambda T.
\]

(iii) On these pseudoterms \( \Lambda T \) two notions of reduction are defined by
(λx:σ.M)N → M [x := N], \hspace{1cm} (β)

(Λα.M)σ → M [α := σ]. \hspace{1cm} (β2)

4.1.2 Convention. \(Λαλx:σΛβ.M\) stands for \(Λα.λx:σ.(Λβ.(M))\).

For example, \((ΛαΛβλx:α λy:β.x)(γ→γ)(∀δ.δ)ab\) is a pseudoterm that reduces in four β2-steps to a.

Assignment rules of \(λ2\) Church.

4.1.3. Definition. \(Γ \vdash_λ M : σ\) is defined by the following axiom and rules

\[
\begin{align*}
(\text{Start}) & \quad Γ \vdash x : σ, \text{ if } (x : σ) \varepsilon Γ; \\
(→E) & \quad Γ \vdash M : (σ→τ) \quad Γ \vdash N : σ \quad \frac{Γ \vdash MN : τ}{Γ \vdash (x.σ)[M] : τ}; \\
(→I) & \quad Γ, x : σ \vdash M : τ \quad \frac{Γ \vdash (λx.M) : (σ→τ)}{}
\end{align*}
\]

\[
\begin{align*}
(∀E) & \quad Γ \vdash M : ∀\alpha.σ \quad \frac{Γ \vdash M : σ \varepsilon \varepsilon [α := τ]}{Γ \vdash (Λα.M) : (∀α.σ)}; \\
(∀I) & \quad Γ \vdash M : σ \quad \frac{Γ \vdash (Λα.M) : (∀α.σ)}{}
\end{align*}
\]

4.1.4. Examples. (i) \(Γ \vdash_λ (Λαλx:α x) : (∀α.α→α)\).

(ii) \(Γ \vdash_λ (Λα Λβ λx:α λy:β.x) : (∀α∀β.α→β→α)\).

(iii) \(Γ \vdash_λ (Λβ x.(⊥→β)x) : (∀β. ⊥→β)\), where \(⊥ = ∀α.α\).

Properties of \(λ2\) Church

4.1.5 Theorem. The following properties are valid for \(λ2\) (see 2.1.5 for the meaning of the acronyms).

(i) CR, for \(ββ2\) - reduction on \(ΛT\).

(ii) SR.

(iii) SN.

(iv) UT.

(v) \(Γ \vdash M : σ?\) is decidable.

(vi) \(Γ \vdash M : ?\) is computable.

Pragmatics of \(λ2\) Church.

In Reynolds [1974] the system \(λ2\) was used to formalise various type-related concepts in programming languages, such as type definitions, abstract data types, and polymorphism. For example, an expression containing a type definition, like

\[\text{type } t = τ \text{ in } e\]

can be represented by the \(λ2\) term \((Λt.e) τ\).

Many programming languages contain some form of abstract data type definition like
abstype \( t \) with \( x : \sigma(t) \) is \( \tau \) with \( e_1 \) in \( e_2 \)

which introduces an "abstract" type \( t \) with operations \( x : \sigma(t) \), together with a "representation" consisting of a "concrete" type \( \tau \) and "concrete" operations \( e_1 \) of type \( \sigma(t) \). In \( \lambda_2 \) such a construct can be modelled by the term

\[
(\Lambda t : \langle \lambda x : \sigma(t), e_2 \rangle) \tau e_1
\]

In extensions of \( \lambda_2 \) with so-called existential or \( \Sigma \) types it is even possible to consider the pair \( (\tau, e_1) \) as a term of type \( \Sigma \cdot \sigma(t) \), the type of representations of the abstract type. Thus representations become first-class citizens. For more information on this view of abstract data types we refer to Mitchell [1985], Cardelli [1985].

For an experimental language based on the Church version of \( \lambda_2 \) and \( \lambda \mu \), see Barendregt and van Leeuwen [1985]. That language (TALE) includes arrays and disjoint sums and its syntax and operational semantics are given in full detail.

The polymorphism provided by \( \lambda_2 \)-Church differs from that of \( \lambda_2 \)-Curry in the presence of explicit abstraction over type variables and application to type expressions. To illustrate the differences we rephrase the map example of section 2 in the system à la Church. The basis remains

\[
\begin{align*}
null : & \forall \alpha. \text{list } \alpha \rightarrow \text{bool} \\
nil : & \forall \alpha. \text{list } \alpha \\
\text{cons} : & \forall \alpha. \alpha \rightarrow \text{list } \alpha \rightarrow \text{list } \alpha \\
\text{hd} : & \forall \alpha. \text{list } \alpha \rightarrow \alpha \\
\text{tl} : & \forall \alpha. \text{list } \alpha \rightarrow \text{list } \alpha \\
\text{if} : & \forall \alpha. \text{bool } \rightarrow \alpha \rightarrow \alpha \rightarrow \alpha
\end{align*}
\]

but the definition of map becomes

\[
\text{letrec map} = (\Lambda \alpha \Lambda \beta \\
. \lambda f : (\alpha \rightarrow \beta) \lambda m : \text{list } \alpha \\
. \text{if list } \beta \\
\text{. (null } \alpha \ m) \\
\text{. (nil } \beta) \\
\text{. (cons } \beta \ (f (\text{hd } \alpha \ m)) \ (\text{map } \alpha \beta f \ (\text{tl } \alpha \ m))) \\
\).)
\]

The differences with the Curry style will be clear. On the positive side, type inference is trivial. On the negative side, terms tend to become cluttered up with type information. For practical purposes one would like to have the best of both worlds, i.e. the conciseness provided by the Curry style and the simplicity of type inference provided by the Church style. Some partial solutions have been presented in McCracken
[1984], Boehm [1989], O'Toole 89 [1989], Pfenning [1988]. Although TALE is explicitly typed, type information may be left out in clearly defined cases when it can be reconstructed.

4.2. TYPE DEPENDENT TYPES

A natural example of a type depending on another type is \( \alpha \rightarrow \alpha \) depending on \( \alpha \). In fact it is natural to define \( f = \lambda \alpha \in T. \alpha \rightarrow \alpha \) such that \( f(\alpha) = \alpha \rightarrow \alpha \). This will be possible in the system \( \lambda \omega \).

Another feature of \( \lambda \omega \) is that types are generated by the system itself and not in the informal metalanguage. There is a constant \( * \) such that \( \sigma : * \) corresponds to \( \sigma \in T \). The informal statement

\[
\alpha, \beta \in T \Rightarrow (\alpha \rightarrow \beta) \in T
\]

now becomes the formal

\[
\alpha : *, \beta : * \vdash (\alpha \rightarrow \beta) : *.
\]

For the \( f \) above we then write \( f = \lambda \alpha : *. \alpha \rightarrow \alpha \). The question arises where this \( f \) lives. Neither on the level of the elements (of types), nor among the types. Therefore a new category \( K \) (of kinds) is introduced

\[
K = * \mid K \rightarrow K.
\]

That is \( K = \{ *, * \rightarrow *, * \rightarrow * \rightarrow *, \ldots \} \). A constant \( \square \) will be introduced such that \( k : \square \) corresponds to \( k \in K \). If \( \vdash k : \square \) and \( \vdash F : k \), then \( F \) is called a constructor of kind \( k \). We will see that

\[
\vdash (\lambda \alpha : *. \alpha \rightarrow \alpha) : (* \rightarrow *), \text{i.e. our } f \text{ is a constructor of kind } * \rightarrow *.
\]

Each element of \( T \) will be a constructor of kind \( * \).

Types and terms of \( \lambda \omega \)

Although types and terms of \( \lambda \omega \) can be kept separate, we will consider them as subsets of one general set \( \mathcal{T} \) of pseudo expressions. This is a preparation to 4.3 and 4.4 in which it is essential that types and terms are being mixed.

4.2.1. Definition. (i) A set of pseudo expressions \( \mathcal{T} \) is defined as follows.

\[
\mathcal{T} = V \mid C \mid \mathcal{T} \cdot \mathcal{T} \mid \lambda V : \mathcal{T} \cdot \mathcal{T} \mid \mathcal{T} \rightarrow \mathcal{T}
\]

(ii) Among the constants \( C \) two elements are selected and given the names \( * \) and \( \square \).

4.2.2. Notation. (i) \( x, y, z, \ldots, \alpha, \beta, \gamma \ldots \) range over \( V \).

(ii) \( a, b, c, \ldots, \alpha, \beta, \gamma \ldots \) range over \( C \).

Assignment rule of \( \lambda \omega \)

Because types and terms come from the same set \( \mathcal{T} \), the definition of statement is modified accordingly. Bases have to become linearly ordered. The reason is that in \( \lambda \omega \) one wants to derive

\[
\alpha : *, x : \alpha \vdash x : \alpha
\]

but not

\[
x : \alpha, \alpha : * \vdash x : \alpha
\]

\[
x : \alpha \vdash (\lambda \alpha : * \cdot x) : (* \rightarrow \alpha)
\]
in which $\alpha$ occurs both free and bound.

4.2.3. Definition. (i) A *statement* of $\lambda_\Omega$ is if the form $M : A$ with $M, A \in \mathcal{T}$.

(ii) A *context* is a finite linearly ordered set of statements with distinct variables as subjects. $\Gamma$, $\Delta, \ldots$ range over contexts.

(iii) $< >$ denotes the empty context. If $\Gamma = < x_1 : A_1, \ldots, x_n : A_n >$ then

$$\Gamma, y : B = < x_1 : A_1, \ldots, x_n : A_n, y : B >.$$  

4.2.4. Definition. The notion $\Gamma \vdash \lambda_\Omega M : A$ is defined by the following axiom and rules. The letter $s$ ranges over $\{*, \square\}$.

(Axiom) $< > \vdash * : \square$;

(Start) $\frac{\Gamma \vdash A : s}{\Gamma, x : A \vdash x : A}$, where $x$ is fresh, i.e. not in $\Gamma$ or $A$;

(Weakening) $\frac{\Gamma \vdash B : C \quad \Gamma \vdash A : s}{\Gamma, x : A \vdash B : C}$, where $x$ is fresh;

(Type/ kind formation) $\frac{\Gamma \vdash A : s \quad \Gamma \vdash B : s}{\Gamma \vdash (A \to B) : s}$;

($\to$E) $\frac{\Gamma \vdash F : (A \to B) \quad \Gamma \vdash a : A}{\Gamma \vdash Fa : B}$;

($\to$I) $\frac{\Gamma \vdash A : s, \Gamma, x : A \vdash B : s \quad \Gamma, x : A \vdash b : B}{\Gamma \vdash (\lambda x : A. b) : (A \to B)}$;

(Conversion rule) $\frac{\Gamma \vdash A : B \quad \Gamma \vdash B : s}{\Gamma \vdash A : B'}$, if $B =_\beta B'$.

4.2.6. Examples. (i) $\alpha : *, \beta : * \vdash \lambda_\Omega (\alpha \to \beta) : *$.

(ii) $\alpha : *, \beta : *, x : (\alpha \to \beta) \vdash \lambda_\Omega x : (\alpha \to \beta)$.

(iii) $\alpha : *, \beta : * \vdash \lambda_\Omega (\lambda x : (\alpha \to \beta). x) : ((\alpha \to \beta) \to (\alpha \to \beta))$.

Write $D =_\beta \lambda \beta : *$. Then the following hold.

(iv) $\vdash \lambda_\Omega D : (\to^* \to^*)$.

(v) $\alpha : * \vdash \lambda_\Omega (\lambda x : D \alpha . x) : D (D \alpha)$.

**Properties of $\lambda_\Omega$**

4.2.7. Theorem. The following results hold for $\lambda_\Omega$.
(i) CR, for reduction on $T$.
(ii) SR.
(iii) SN, i.e. $\Gamma \vdash M : A \Rightarrow SN(M) \& SN(A)$.
(iv) UT, i.e. $\Gamma \vdash M : A \& \Gamma \vdash M : A' \Rightarrow A =_\beta A'$.
(v) $\Gamma \vdash M : ?$ is decidable.
(vi) $\Gamma \vdash M : ?$ is computable.

**Pragmatics of $\lambda_\omega$**

The relevance of $\lambda_\omega$ for programming languages is that the system permits computations with types and definitions of type constructors. Consider the following example.

4.2.8. Example.

If we assume constructor declarations

\[
\begin{align*}
1 : * & \quad \text{int} : * \\
\times : * \to * \to * & \quad \text{bool} : * \\
+ : * \to * \to * & \\
\end{align*}
\]

and recursive types of the form $\mu \alpha : * . \sigma$ similarly to section 3.2. we can from the type of integer lists as $\mu \beta : *. 1 + \text{int} \times \beta$.

The 1 stands for the singleton type \{nil\}. Similarly for boolean lists we take $\mu \beta : *. 1 + \text{bool} \times \beta$.

These two types can be obtained by applying a certain constructor of kind $* \to *$ to int and bool respectively, viz. the constructor

\[
(\lambda \alpha : * . \mu \beta : *. 1 + \alpha \times \beta) : * \to *.
\]

Using a let definition mechanism for constructors, we can form the type of functions form integer lists to boolean lists as

\[
\begin{align*}
\text{let list} & = (\lambda \alpha : *. \mu \beta : *. 1 + \alpha \times \beta) \\
\text{in list int} & \to \text{list bool}
\end{align*}
\]

which is an abbreviation for

\[
(\lambda \text{list} : * \to *. \text{list int} \to \text{list bool}) (\lambda \alpha : \text{type } \mu \beta : *. 1 + \alpha \times \beta)
\]

where

\[
(\lambda \text{list} : * \to *. \text{list int} \to \text{list bool}) : (* \to *) \to *
\]

and which $\beta$-reduces to

\[
(\lambda \alpha : * . \mu \beta : *. 1 + \alpha \times \beta) \text{ int} \to (\lambda \alpha : * . \mu \beta : *. 1 + \alpha \times \beta) \text{ bool}
\]

and subsequently to

\[
(\mu \beta : *. 1 + \text{int} \times \beta) \to (\mu \beta : *. 1 + \text{bool} \times \beta).
\]

The let -construction in the example above is of the form $\text{let } \alpha = \rho \text{ in } \sigma$ which is an abbreviation for

\[
(\lambda \alpha : k. \sigma) \rho
\]
where \( \sigma \) and \( \rho \) are both constructors. In order to have the full benefit of the definition facility for constructors we also need
\[
\text{let } \alpha = \rho \text{ in } M
\]
which is an abbreviation for
\[
(\lambda \alpha : k . M) \rho
\]
where \( \rho \) is a constructor and \( M \) is a term. This construction is not well-formed in \( \lambda \omega \). It can be formed in the system \( \lambda 2 \) in the special case that \( k = * \). The wish to form terms \( (\lambda \alpha : k . M) \) where \( k \) is an arbitrary kind leads to the system \( \lambda \omega \), which is the "union" of \( \lambda \omega \) and \( \lambda 2 \). The system \( \lambda \omega \) will be defined in section 4.4.

4.3 ELEMENT DEPENDENT TYPES

An intuitive example of a type depending on an element is \( A^n \rightarrow B \) with \( n \in \text{Int} \). In order to formalise the possibility of such "dependent types" in the system \( \lambda P \), the notion of kind is extended such that if \( A \) is a type and \( k \) is a kind, then \( A \rightarrow k \) is a kind. In particular \( A \rightarrow * \) is a kind. Then if \( f : A \rightarrow * \) and \( a : A \), one has \( fa : * \). This \( fa \) is a dependent type.

Another idea important for a system with dependent types is the formation of cartesian products. Suppose that for each \( a : A \) a type \( B_a \) is given and that there is an element \( b_a : B_a \). Then we may form the function \( \lambda a : A . b_a \) which has as type the cartesian product \( \Pi a : A . B_a \) of the \( B_a \)'s. The formation of function spaces \( A \rightarrow B \) can be seen as a particular instance of cartesian products. Indeed,
\[
A \rightarrow B \equiv \Pi a : A . B (\equiv B^A \text{ informally})
\]
provided that \( a \) does not occur (freely) in \( B \). This is similar to the fact that a power of numbers is a constant product
\[
\prod_{i=1}^{3} b_i = b_1 b_2 b_3 = b^3
\]
provided that \( b_1 = b_2 = b_3 = b \). Therefore the type constructor \( \rightarrow \) can be left out in the presence of \( \Pi \).

Types and terms of \( \lambda P \).

4.3.1 Definition. (i) The set of pseudo expressions of \( \lambda P \), notation \( T \), is defined as follows.
\[
T = \forall | C | \top \top | \lambda \forall \top \top | \Pi \forall \top \top
\]
(ii) Among the constants \( C \) two elements are called * and \( \Box \).

Assignment rules for \( \lambda P \)

Statements and contexts are defined as for \( \lambda \omega \) (statements are of the form \( M : A \) with \( M, A \in T \); contexts are finite linearly ordered sets of statements).

4.3.2. Definition. The notion \( \Gamma \vdash \lambda P M : A \) is defined by the following axiom and rules. Again the letter \( s \) ranges over \( \{ *, \Box \} \).
(Axiom) \[ \langle \rangle \vdash * : \square; \]

(Start) \[ \Gamma \vdash A : s, \text{ where } x \text{ is fresh}; \]
\[ \Gamma, x: A \vdash x : A \]

(Weakening) \[ \Gamma \vdash B : C \quad \Gamma \vdash A : s, \text{ where } x \text{ is fresh}; \]
\[ \Gamma, x: A \vdash B : C \]

(Type/kind formation) \[ \Gamma \vdash A : * \quad \Gamma, x: A \vdash B : s; \]
\[ \Gamma \vdash (\Pi x: A. B) : s \]

(→I) \[ \Gamma \vdash A : * \quad \Gamma, x: A \vdash B : s \quad \Gamma, x: A \vdash b : B; \]
\[ \Gamma \vdash (\lambda x: A. b) : (\Pi x: A. B) \]

(→E) \[ \Gamma \vdash F : (\Pi x: A. B) \quad \Gamma \vdash a : A; \]
\[ \Gamma \vdash Fa : B[x := a] \]

(Conversion) \[ \Gamma \vdash A : B \quad \Gamma \vdash B' : s, \text{ if } B =_\beta B'. \]

4.3.3. Examples. In \( \lambda P \) the following hold.

(i) \[ A : * \vdash (A \rightarrow *) : \square. \]

(ii) \[ A : *, P : (A \rightarrow *), a : A \vdash Pa : *. \]

(iii) \[ A : *, P : (A \rightarrow *), a : A \vdash (Pa \rightarrow *) : \square. \]

(iv) \[ A : *, P : (A \rightarrow *) \vdash (\Pi a : A. Pa \rightarrow *) : \square. \]

(v) \[ A : *, P : (A \rightarrow *) \vdash (\lambda a : A \lambda p : Pa.p) : (\Pi a : A. Pa \rightarrow Pa). \]

Properties of \( \lambda P \).

4.3.4. Theorem. The following results hold for \( \lambda P \).

(i) \( \text{CR, for reduction on } \mathcal{T}. \)

(ii) \( \text{SR.} \)

(iii) \( \text{SN, i.e. } \Gamma \vdash M : A \Rightarrow \text{SN}(M) \& \text{SN}(A). \)

(iv) \( \text{UT.} \)

(v) \( \Gamma \vdash M : A \) is decidable.

(vi) \( \Gamma \vdash M : ? \) is computable.

Pragmatics of \( \lambda P \)

Systems like \( \lambda P \) have been introduced by N.G. de Bruijn [1970], [1980] in order to represent mathematical theorems and their proofs. The method is as follows.
One assumes there is a set \( \text{prop} \) of propositions that is closed under implication. This is done by taking as context \( \Gamma_0 \) defined as

\[
\text{prop} : *, \text{imp} : \text{prop} \rightarrow \text{prop} \rightarrow \text{prop}.
\]

Write \( \varphi \supset \psi \) for \( \text{imp} \varphi \psi \). In order to express that a proposition is valid a \( T : \text{prop} \rightarrow * \) is assumed and \( \varphi : \text{prop} \) is defined to be valid if \( T\varphi \) is inhabited, i.e. \( M : T\varphi \) for some \( M \). Now in order to express that implication has the right properties, one assumes \( \supset_e \) and \( \supset_i \) such that

\[
\supset_e \varphi \psi : T(\varphi \supset \psi) \rightarrow T\varphi \rightarrow T\psi.
\]

\[
\supset_i \varphi \psi : T\varphi \rightarrow T\psi \rightarrow T(\varphi \supset \psi).
\]

So for the representation of implicational proposition logic one wants to work in context \( \Gamma_{\text{prop}} \) consisting of \( \Gamma_0 \) followed by

\[
T : \text{prop} \rightarrow *
\]

\[
\supset_e : \Pi \varphi : \text{prop} \Pi \psi : \text{prop}. T(\varphi \supset \psi) \rightarrow T\varphi \rightarrow T\psi
\]

\[
\supset_i : \Pi \varphi : \text{prop} \Pi \psi : \text{prop}. (T\varphi \rightarrow T\psi) \rightarrow T(\varphi \supset \psi).
\]

As an example we want to formulate that \( \varphi \supset \varphi \) is valid for all propositions. The translation as type is \( T(\varphi \supset \varphi) \) which indeed is inhabited

\[
\Gamma_{\text{prop}} \vdash \lambda \varphi : T(\varphi \supset \varphi).
\]

(Note that since \( \vdash T\varphi : * \) one has \( \vdash (\lambda \varphi : T\varphi. x) : (T\varphi \rightarrow T\varphi) \).)

Having formalised many valid statements de Bruijn realised that it was rather tiresome to carry around the \( T \). He therefore proposed to use \( * \) itself for \( \text{prop} \), the constructor \( \rightarrow \) for \( \supset \) and the identity for \( T \). Then for \( \supset_e \varphi \psi \) one can use

\[
\lambda x : (\varphi \supset \psi) \lambda y : \varphi. xy
\]

and for \( \supset_i \varphi \psi \)

\[
\lambda x : (\varphi \supset \psi). x.
\]

In this way the \( \{ \rightarrow, \forall \} \) fragment of (manysorted constructive) predicate logic can be interpreted too. A predicate \( P \) on a set (type) \( A \) can be represented as a \( P : A \rightarrow * \) and for \( a : A \) one defines \( Pa \) to be valid if it is inhabited. Quantification \( \forall x : A. Px \) is translated as \( \Pi x : A. Px \). Now a formula

\[
\forall x : A. \forall y : A. Px \rightarrow \forall x : A. Px
\]

can be seen to be valid because its translation is inhabited

\[
A : *, P : A \rightarrow * \vdash (\lambda z : (\Pi x : A. \Pi y : A. Px)y. \lambda x : A. zxx) : (\Pi x : A. \Pi y : A. Px \rightarrow \Pi x : A. Px).
\]

The system \( \lambda P \) is given that name because predicate logic can be interpreted in it. The method interprets propositions (or formulas) as types and proofs as inhabiting terms and is the basis of several languages in the family AUTOMATH designed and implemented by de Bruijn and co-workers for the automatic verification of proofs. Similar projects inspired by AUTOMATH are described in Constable et al. [1986] (NUPRL), Harper et al. [1987] (LF) and Coquand et al. [1989] (calculus of constructions). The project LF uses the interpretation of formulas using \( T : \text{prop} \rightarrow * \) like the original use in AUTOMATH.
4.4 GENERALIZED TYPE SYSTEMS

So far we have introduced four systems of typed lambda calculus à la Church, viz. $\lambda\rightarrow$, $\lambda\rightarrow\lambda\omega$ and $\lambda\rightarrow\lambda\eta$. Although it may not seem so, there is a uniform way of describing these systems. We will define the notation 'generalised type system' (GTS) and show how the four systems in question are particular cases. The differentiation of systems is obtained by controlling which abstractions are allowed.

4.4.1. Definition. (i) The set of pseudo expressions of a GTS, notation $\mathcal{T}$

$$\mathcal{T} = V \cup C \cup \ell \cup \Pi \cup \nu \cup \lambda V : \ell \cup \Pi V : \ell$$

(ii) A statement of a GTS is of the form $M : A$ with $M, A \in \mathcal{T}$. $M$ is called the subject and $A$ the predicate.

(iii) A context is a finite linearly ordered sequence of statements with as subjects distinct variables.

4.4.2. Definition. A specification of a GTS is a triple $\mathcal{S} = (S, A, R)$ such that

- $S \subseteq C$, the elements of $S$ are called sorts
- $A$ is a set of statements of the form $c : s$ with $c \in C$ and $s \in S$; the elements of $A$ are called axioms.
- $R$ is a set of pairs of the form $(s_1, s_2)$ with $s_1, s_2 \in S$; the elements of $R$ are called rules.

4.4.3. Definition. Given a specification of a GTS $\mathcal{S} = (S, A, R)$, the corresponding GTS, notation $\lambda \mathcal{S}$, derives statements relative to a context $\Gamma$. The rules $(s_1, s_2) \in R$ determine which abstraction are allowed.

(Axiom) $\Gamma \vdash c : s$, if $(c : s) \in A$

(Start) $\Gamma, x : A \vdash x : A$

(Weakening) $\Gamma \vdash B : C$, $\Gamma \vdash s : s'$, if $s \in S$ and $x$ is fresh;

$\Gamma, x : A \vdash B : C$

($\Pi$-elimination) $\Gamma \vdash F : (\Pi x : A. B)$, $\Gamma \vdash a : A$;

$\Gamma \vdash F_a : B[x := a]$

($\Pi$-formation) $\Gamma \vdash A : s_1$, $\Gamma, x : A \vdash B : s_2$, if $(s_1, s_2) \in R$;

$\Gamma \vdash (\Pi x : A. B) : s_2$

($\Pi$-introduction) $\Gamma \vdash A : s_1$, $\Gamma, x : A \vdash B : s_2$, $\Gamma, x : A \vdash b : B$;

$\Gamma \vdash (\lambda x : A. b) : (\Pi x : A. B)$, if $(s_1, s_2) \in R$.
(Conversion) \[
\frac{\Gamma \vdash A : B \quad \Gamma \vdash B' : s}{\Gamma \vdash A : B'}
\], if se S and B =pB'.

4.4.4. Examples.
(i) Consider the following specification
\[ S = \{*, \square\} \]
\[ A = \{*: \square\} \]
\[ R = \{(*,\ast), (\ast, \square)\} \]
Such a specification is written stylistically as
\[
\begin{array}{c}
S \ast, \square \\
A \ast: \square \\
R (\ast,\ast), (\ast, \square)
\end{array}
\]
This system \(\lambda(S, A, R)\) is the same as \(\lambda P\).
(ii) Consider
\[
\begin{array}{c}
S \ast, \square \\
A \ast: \square \\
R (\ast,\ast), (\square, \square)
\end{array}
\]
Then \(\lambda(S, A, R)\) is \(\lambda \emptyset\).

4.4.5. Proposition.
(i) Consider the following specification
\[
\begin{array}{c}
S \ast, \square \\
A \ast: \square \\
R (\ast,\ast)
\end{array}
\]
Then \(\lambda(S, A, R)\) is in fact \(\lambda \rightarrow\).
(ii) Consider the following specification.
\[
\begin{array}{c}
S \ast, \square \\
A \ast: \square \\
R (\ast,\ast), (\square, \ast)
\end{array}
\]
Then \(\lambda(S, A, R)\) is \(\lambda 2\).

Proof idea. (i) By induction on the generation of \(\vdash\) it can be shown that if \(\Gamma \vdash (\Pi x : A . B) : \ast\), then \(x \notin \text{FV}(B)\). Therefore each \(\Pi x : A . B\) is in fact \(A \rightarrow B\).

(ii) Similarly. \(\square\)

By making variations in the GTS's introduced in 4.4.4. and 4.4.5. a natural cube of eight GTS's can be defined.
4.4.6. Definition (\(\lambda\)-cube). A set of eight GTS's will be defined. Each systems has as sorts \(S = \{*, \square\}\) and as axioms \(A = \{*, \square\}\). As rules the systems have \((*,*)\) plus one of the eight subsets of \(((*,\square)), (\square,*), (\square,\square)\). The following list gives the correspondence between systems and subsets; also alternative names of a system are given.

<table>
<thead>
<tr>
<th>System</th>
<th>Rules besides ((<em>,</em>))</th>
<th>Alternative names</th>
</tr>
</thead>
<tbody>
<tr>
<td>(\lambda\rightarrow)</td>
<td>((\square,*))</td>
<td>simply typed lambda calculus</td>
</tr>
<tr>
<td>(\lambda2)</td>
<td>((\square,*))</td>
<td>F, F2</td>
</tr>
<tr>
<td>(\lambda\omega)</td>
<td>((\square,\square))</td>
<td></td>
</tr>
<tr>
<td>(\lambda),</td>
<td>((*,\square))</td>
<td>(F_\omega)</td>
</tr>
<tr>
<td>(\lambda)</td>
<td>((\square,*)) ((\square,\square))</td>
<td>LF (logical framework)</td>
</tr>
<tr>
<td>(\lambdaP)</td>
<td>((\square,*)) ((\square,\square))</td>
<td></td>
</tr>
<tr>
<td>(\lambdaP2)</td>
<td>((\square,*)) ((\square,\square))</td>
<td></td>
</tr>
<tr>
<td>(\lambdaP\omega)</td>
<td>((\square,<em>)) ((\square,\square)) ((</em>,\square))</td>
<td>(\lambda C); calculus of constructions</td>
</tr>
</tbody>
</table>

In the following picture of the \(\lambda\)-cube the edges \(\rightarrow\) represent inclusion of systems.

```
  \(\lambda\rightarrow\)  \(\lambda2\)  \(\lambda\omega\)  \(\lambda\),  \(\lambdaP\)
  \(\lambda\)  \(\lambdaP2\)  \(\lambdaP\omega\)
```

The \(\lambda\)-cube.

The systems \(\lambda\rightarrow\), \(\lambda2\), \(\lambda\omega\) and \(\lambda\) can be seen as spanning the \(\lambda\)-cube. E.g. \(\lambda\omega\) is the union of \(\lambda2\) and \(\lambda\omega\). The system \(\lambda\omega = F_\omega\) was introduced in Girard [1972]. The system \(\lambdaP\omega\) is the calculus of constructions of Coquand and Huet [1988]. The \(\lambda\)-cube is introduced in Barendregt [1989] and is a finestructure of \(\lambdaP\omega\). The notion of GTS is a generalisation of the \(\lambda\)-cube due indepently to Berardi and Terlouw (personal communication).

4.4.7. Theorem. All systems of the \(\lambda\)-cube enjoy the following properties.

(i) CR.
(ii) SR.
(iii) SN.
(iv) SN, i.e. \(\Gamma \vdash M : A \Rightarrow SN(M) \& SN(A)\).
(v) UT, i.e. \(\Gamma \vdash M : A \& \Gamma \vdash M : A' \Rightarrow A = A'\).
(vi) \(\Gamma \vdash M : A?\) is decidable.
(vii) $\Gamma \vdash M : ?$ is computable.

There are also other interesting GTS's. For example

\[
\begin{align*}
S & \ast \\
A & \ast : \ast \\
R & (\ast, \ast)
\end{align*}
\]

specifies the system $\lambda \ast$ in which every type is inhabited and not all legal terms are normalising. As remarked by H. Geuvers the following GTS

\[
\begin{align*}
S & \ast, \Box, \Delta \\
A & \ast : \Box, \Box : \Delta \\
R & (\ast, \ast), (\Box, \ast)
\end{align*}
\]

specifies $\lambda HOL$, a GTS equivalent to higher order logic as in Church [1941]; the $k$ in $\square$ are used as sets. See Barendregt [1989], [1990] and Barendregt and Dekkers [199-] for more information on GTS's.
