Search for supersymmetry in events with $b$-tagged jets and missing transverse momentum in $pp$ collisions at $\sqrt{s} = 13$ TeV with the ATLAS detector

The ATLAS collaboration

E-mail: atlas.publications@cern.ch

ABSTRACT: A search for the supersymmetric partners of the Standard Model bottom and top quarks is presented. The search uses 36.1 fb$^{-1}$ of $pp$ collision data at $\sqrt{s} = 13$ TeV collected by the ATLAS experiment at the Large Hadron Collider. Direct production of pairs of bottom and top squarks ($\tilde{b}_1$ and $\tilde{t}_1$) is searched for in final states with $b$-tagged jets and missing transverse momentum. Distinctive selections are defined with either no charged leptons (electrons or muons) in the final state, or one charged lepton. The zero-lepton selection targets models in which the $\tilde{b}_1$ is the lightest squark and decays via $\tilde{b}_1 \rightarrow b\tilde{\chi}_1^0$, where $\tilde{\chi}_1^0$ is the lightest neutralino. The one-lepton final state targets models where bottom or top squarks are produced and can decay into multiple channels, $\tilde{b}_1 \rightarrow b\tilde{\chi}_1^0$ and $\tilde{b}_1 \rightarrow t\tilde{\chi}_1^\pm$, or $\tilde{t}_1 \rightarrow t\tilde{\chi}_1^0$ and $\tilde{t}_1 \rightarrow b\tilde{\chi}_1^\pm$, where $\tilde{\chi}_1^\pm$ is the lightest chargino and the mass difference $m_{\tilde{\chi}_1^\pm} - m_{\tilde{\chi}_1^0}$ is set to 1 GeV. No excess above the expected Standard Model background is observed. Exclusion limits at 95% confidence level on the mass of third-generation squarks are derived in various supersymmetry-inspired simplified models.

1 Introduction

Supersymmetry (SUSY) [1–6] provides an extension of the Standard Model (SM) that solves the hierarchy problem [7–10] by introducing partners of the known bosons and fermions. In the framework of $R$-parity-conserving models, SUSY particles are produced in pairs and the lightest supersymmetric particle (LSP) is stable, providing a possible candidate for dark matter [11, 12]. In a large variety of models the LSP is the lightest neutralino ($\chi^0_1$). Naturalness considerations [13, 14] suggest that the supersymmetric partners of the third-generation SM quarks are the lightest coloured supersymmetric particles. This may lead to the lightest bottom squark ($\tilde{b}_1$) and top squark ($\tilde{t}_1$) mass eigenstates$^1$ being significantly lighter than the other squarks and the gluinos. As a consequence, $\tilde{b}_1$ and $\tilde{t}_1$ could be pair-produced with relatively large cross-sections at the Large Hadron Collider (LHC).

$^1$Scalar partners of the left-handed and right-handed chiral components of the bottom quark ($\tilde{b}_{L,R}$) or top quark ($\tilde{t}_{L,R}$) mix to form mass eigenstates for which $\tilde{b}_1$ and $\tilde{t}_1$ are defined as the lighter of the two.
This paper presents a search for the direct pair production of bottom and top squarks decaying into final states with jets, two of them originating from the fragmentation of $b$-quarks ($b$-jets), and missing transverse momentum ($p_T^{\text{miss}}$, whose magnitude is referred to as $E_T^{\text{miss}}$). The dataset analysed corresponds to 36.1 fb$^{-1}$ of proton-proton ($pp$) collisions data at $\sqrt{s} = 13$ TeV collected by the ATLAS experiment during Run 2 of the LHC in 2015 and 2016. The third-generation squarks are assumed to decay to the lightest neutralino (LSP) directly or through one intermediate stage. The search is based on simplified models inspired by the minimal supersymmetric extension of the SM (MSSM) [15–17], where the $\tilde{b}_1$ exclusively decays as $\tilde{b}_1 \to b \tilde{\chi}^0_1$ or where two decay modes for the bottom (top) squark are allowed and direct decays to the LSP, $\tilde{b}_1 \to b \tilde{\chi}^0_1$ ($\tilde{t}_1 \to t \tilde{\chi}^0_1$) compete with decays via an intermediate chargino ($\tilde{\chi}^\pm_1$) state, $\tilde{b}_1 \to t \tilde{\chi}^+_1$ ($\tilde{t}_1 \to b \tilde{\chi}^+_1$). In this case it is assumed that the $\tilde{\chi}^+_1$ is the next-to-lightest supersymmetric particle (NLSP) and is almost degenerate with $\tilde{\chi}^0_1$, such that other decay products are too low in momentum to be efficiently reconstructed. The first set of models lead to final-state events from bottom squark pair production characterized by the presence of two $b$-jets, $E_T^{\text{miss}}$ and no charged leptons ($\ell = e, \mu$), referred to as the zero-lepton channel (figure 1a). For mixed decays models (intended as models where both direct decays and decays through an intermediate stage are kinematically allowed), the final state of bottom or top squark pair production depends on the branching ratios of the competing decay modes. If the decay modes are equally probable, a large fraction of the signal events are characterized by the presence of a top quark, a bottom quark, and neutralinos. Hadronic decays of the top quark are targeted by the zero-lepton channel, whilst novel dedicated selections requiring one charged lepton, two $b$-jets and $E_T^{\text{miss}}$ are developed for semi-leptonic decays of the top quark, referred to as the one-lepton channel (figure 1b). A statistical combination of the two channels is performed when interpreting the results in terms of exclusion limits on the third-generation squark masses.

Previous searches for the exclusive decay $\tilde{b}_1 \to b \tilde{\chi}^0_1$ with the $\sqrt{s} = 13$ TeV LHC Run-2 dataset at ATLAS and CMS have set exclusion limits at 95% confidence level (CL) on $\tilde{b}_1$ masses in such scenarios [18, 19]. Searches in the context of mixed-decay models were performed only by ATLAS using the Run-1 $\sqrt{s} = 8$ TeV dataset and resulted in exclusion limits on the third-generation squark mass that depend on the branching ratios of the competing decay modes [20].

2 ATLAS detector

The ATLAS detector [21] is a multi-purpose particle physics detector with a forward-backward symmetric cylindrical geometry and nearly 4$\pi$ coverage in solid angle.\footnote{ATLAS uses a right-handed coordinate system with its origin at the nominal interaction point in the centre of the detector. The positive $x$-axis is defined by the direction from the interaction point to the centre of the LHC ring, with the positive $y$-axis pointing upwards, while the beam direction defines the $z$-axis. Cylindrical coordinates $(r, \phi)$ are used in the transverse plane, $\phi$ being the azimuthal angle around the $z$-axis. The pseudorapidity $\eta$ is defined in terms of the polar angle $\theta$ by $\eta = -\ln \tan(\theta/2)$. Rapidity is defined as $y = 0.5 \ln ([E + p_z] / [E - p_z])$ where $E$ denotes the energy and $p_z$ is the component of the momentum along the beam direction.} The

(b) 

Figure 1. Diagrams illustrating the most relevant signal scenarios considered for the pair production of bottom and top squarks targeted by the (a) zero-lepton and (b) one-lepton channel selections. In (a) bottom squarks decay to a bottom quark and the lightest neutralino. In (b), decays via intermediate charginos are kinematically available and compete. If the mass difference \( \Delta m(\tilde{\chi}_1^\pm, \tilde{\chi}_1^0) \) is small, the \( W \) bosons from chargino decays are off-shell.

inner tracking detector consists of pixel and silicon microstrip detectors covering the pseudorapidity region \( |\eta| < 2.5 \), surrounded by a transition radiation tracker which enhances electron identification in the region \( |\eta| < 2.0 \). Between Run 1 and Run 2, a new inner pixel layer, the insertable B-layer [22], was added at a mean sensor radius of 3.3 cm. The inner detector is surrounded by a thin superconducting solenoid providing an axial 2 T magnetic field and by a fine-granularity lead/liquid-argon (LAr) electromagnetic calorimeter covering \( |\eta| < 3.2 \). A steel/scintillator-tile calorimeter provides hadronic coverage in the central pseudorapidity range \( (|\eta| < 1.7) \). The endcap and forward regions \( (1.5 < |\eta| < 4.9) \) of the hadronic calorimeter are made of LAr active layers with either copper or tungsten as the absorber material. An extensive muon spectrometer with an air-core toroidal magnet system surrounds the calorimeters. Three layers of high-precision tracking chambers provide coverage in the range \( |\eta| < 2.7 \), while dedicated fast chambers allow triggering in the region \( |\eta| < 2.4 \). The ATLAS trigger system consists of a hardware-based level-1 trigger followed by a software-based high-level trigger [23].

3 Data and simulated event samples

The data used in this analysis were collected by the ATLAS detector in \( pp \) collisions at the LHC with a centre-of-mass energy of 13 TeV and a 25 ns proton bunch crossing interval during 2015 and 2016. The full dataset corresponds to an integrated luminosity of 36.1 fb\(^{-1}\) after requiring that all detector subsystems were operational during data recording. The uncertainty in the combined 2015+2016 integrated luminosity is 3.2%. It is derived following a methodology similar to that detailed in ref. [24] from a preliminary calibration of the luminosity scale using \( x-y \) beam-separation scans performed in August 2015 and May 2016. Each event includes on average 13.7 and 24.9 inelastic \( pp \) collisions ("pile-up") in the same bunch crossing in the 2015 and 2016 dataset, respectively. In the zero-lepton channel, events are required to pass an \( E_\text{T}^{\text{miss}} \) trigger [25]. This trigger is
fully efficient for events passing the preselection defined in section 5, which requires the offline reconstructed $E_T^{\text{miss}}$ to exceed 200 GeV. Events in the one-lepton channel, as well as events used for control regions, are selected online by a trigger requiring the presence of one electron or muon. The online selection thresholds are such that a plateau of the efficiency is reached for charged-lepton transverse momenta of 27 GeV and above.

Monte Carlo (MC) samples of simulated events are used to model the signal and to aid in the estimation of SM background processes, except multijet processes, which are estimated from data only.

All simulated samples were produced using the ATLAS simulation infrastructure [26] using GEANT4 [27], or a faster simulation [28] based on a parameterization of the calorimeter response and GEANT4 for the other detector systems. The simulated events are reconstructed with the same algorithm as that used for data.

SUSY signal samples were generated with MadGraph5_aMC@NLO [29] v2.2.3 at leading order (LO) and interfaced to PYTHIA v8.186 [30] with the A14 [31] set of tuned parameters (tune) for the modelling of the parton showering (PS), hadronization and underlying event. The matrix element (ME) calculation was performed at tree level and includes the emission of up to two additional partons. The ME-PS matching was done using the CKKW-L [32] prescription, with a matching scale set to one quarter of the third-generation squark mass. The NNPDF23LO [33] parton distribution function (PDF) set was used. The cross-sections used to evaluate the signal yields are calculated to next-to-leading-order (NLO) accuracy in the strong coupling constant, adding the resummation of soft gluon emission at next-to-leading-logarithmic accuracy (NLO+NLL) [34–36]. The nominal cross-section and uncertainty are taken as the midpoint and half-width of an envelope of cross-section predictions using different PDF sets and factorization and renormalization scales, as described in ref. [37].

SM background samples were simulated using different MC event generator programs depending on the process. The generation of $t\bar{t}$ was performed by the Powheg-Box [38] v2 generator with the CT10 [39] PDF set for the matrix element calculations. Single-top-quark events in the $Wt$, $s\bar{t}$, and $t\bar{s}$ channels were generated using the Powheg-Box v1 generator. For all processes involving top quarks, top quark spin correlations were preserved. The parton shower, fragmentation and the underlying event were simulated using PYTHIA v6.428 [40] with the CTEQ6L1 PDF set and the Perugia 2012 [41] tune for the underlying event. The $h_{\text{damp}}$ parameter in Powheg, which controls the $p_T$ of the first additional emission beyond the Born level and thus regulates the $p_T$ of the recoil emission against the $t\bar{t}$ system, was set to the mass of the top quark ($m_t = 172.5$ GeV). All events with at least one leptonically decaying $W$ boson are retained. Fully hadronic $t\bar{t}$ and single-top events do not contain sufficient $E_T^{\text{miss}}$ to contribute significantly to the background. The $t\bar{t}$ samples are normalized using their next-to-NLO (NNLO) cross-section including the resummation of soft gluon emission at next-to-NLL accuracy using Top++2.0 [42]. Samples of single-top-quark events are normalized using the NLO cross-sections reported in refs. [43–45] for the $s\bar{t}$, $t\bar{s}$ and $Wt$-channels, respectively.

Events containing $W$ or $Z$ bosons with associated jets, including jets from the fragmentation of $b$- and $c$-quarks, were simulated using the Sherpa v2.2.1 [46] generator.
Matrix elements were calculated for up to two additional partons at NLO and four partons at LO using the Comix [47] and OpenLoops [48] matrix element event generators and merged with the Sherpa PS [49] using the ME+PS@NLO prescription [50]. The NNPDF30NNLO [33] PDF set was used in conjunction with a dedicated PS tune developed by the Sherpa authors. Additional Sherpa Z+jets samples were produced with similar settings but with up to four partons LO, for the γ+jets studies detailed in section 6. The W/Z+jets events are normalized using their NNLO QCD theoretical cross-sections [51].

Diboson processes were also simulated using the Sherpa generator using the NNPDF30NNLO PDF set in conjunction with a dedicated PS tune developed by the Sherpa authors. They were calculated for up to one (ZZ) or zero (WW, WZ) additional partons at NLO and up to three additional partons at LO. Additional contributions to the SM backgrounds in the signal regions arise from the production of top quark pairs in association with W/Z/h bosons and possibly additional jets. The production of top quark pairs in association with electroweak vector bosons (W, Z) or Higgs bosons was modeled by samples generated at NLO using MadGraph5_aMC@NLO v2.2.3 and showered with Pythia v8.212. Other potential sources of backgrounds, such as the production of three or four top quarks or three gauge bosons, are found to be negligible.

For all samples, except the ones generated using Sherpa, the EvtGen v1.2.0 program [52] was used to simulate the properties of the bottom- and charm-hadron decays. In-time and out-of-time pile-up interactions from the same or nearby bunch-crossings were simulated by overlaying additional pp collisions generated by Pythia v8.186, with the MSTW2008LO [53] PDF set, superimposed onto the hard-scattering events to reproduce the observed distribution of the average number of interactions per bunch crossing [54].

Several samples produced without detector simulation are employed to estimate systematic uncertainties associated with the specific configuration of the MC event generators used for the nominal SM background samples. They include variations of the renormalization and factorization scales, the CKKW-L matching scale, as well as different PDF sets and fragmentation/hadronization models. Details of the MC modelling uncertainties are discussed in section 7.

4 Event reconstruction

The search for pair production of bottom and top squarks is based on two distinct selections of events with b-jets and large missing transverse momentum, with either no charged leptons in the final state, or requiring exactly one electron or muon (for details, see section 5). For the zero-lepton channel selection, events containing charged leptons are explicitly vetoed in the signal and validation regions. Events characterized by the presence of exactly one electron or muon with transverse momentum above 27 GeV are retained in the one-lepton selection and are also used to define control regions for the zero-lepton channel. Finally, same-flavour opposite-sign (SFOS) two-lepton (electron or muon) events with dilepton invariant mass near the Z boson mass are used for control regions employed to aid in the estimation of the Z+jets background for the zero-lepton channel. The details of the reconstruction and selection, as well as the overlap removal procedure are given below.
Selected events are required to have a reconstructed primary vertex consistent with the beamspot envelope and to consist of at least two tracks in the inner detector with $p_T > 0.4$ GeV. When more than one such vertex is found, the one with the largest sum of the squares of transverse momenta of associated tracks [55] is chosen.

Jet candidates are reconstructed from three-dimensional energy clusters [56] in the calorimeter using the anti-$k_t$ jet algorithm [57, 58] with a radius parameter of 0.4. The reconstructed jets are then calibrated to the particle level by the application of a jet energy scale (JES) derived from $\sqrt{s} = 13$ TeV data and simulation [59]. Quality criteria are imposed to identify jets arising from non-collision sources or detector noise, and any event containing such a jet is removed [60]. Further track-based selections are applied to reject jets with $p_T < 60$ GeV and $|\eta| < 2.4$ that originate from pile-up interactions [61], and the jet momentum is corrected by subtracting the expected average energy contribution from pile-up using the jet area method [62]. Jets are classified as “baseline” and “signal”. Baseline jets are required to have $p_T > 20$ GeV and $|\eta| < 4.8$. Signal jets, selected after resolving overlaps with electrons and muons, are required to pass the stricter requirement of $p_T > 35$ GeV and $|\eta| < 2.8$.

Jets are identified as $b$-jets if tagged by a multivariate algorithm which uses information about the impact parameters of inner detector tracks matched to the jet, the presence of displaced secondary vertices, and the reconstructed flight paths of $b$- and $c$-hadrons inside the jet [63]. The $b$-tagging working point with a 77% efficiency, as determined in a sample of simulated $t\bar{t}$ events, was chosen as part of the optimization procedure. The corresponding rejection factors against jets originating from $c$-quarks and from light quarks and gluons at this working point are 6.2 and 134, respectively [64]. To compensate for differences between data and MC simulation in the $b$-tagging efficiencies and mis-tag rates, correction factors are derived from data and applied to the samples of simulated events [63]. Candidate $b$-jets are required to have $p_T > 20$ GeV and $|\eta| < 2.5$.

Electron candidates are reconstructed from energy clusters in the electromagnetic calorimeter matched to a track in the inner detector and are required to satisfy a set of “loose” quality criteria [65–67]. They are also required to lie within the fiducial volume $|\eta| < 2.47$. Muon candidates are reconstructed by matching tracks in the inner detector with tracks in the muon spectrometer. Events containing one or more muon candidates that have a transverse (longitudinal) impact parameter with respect to the primary vertex larger than 0.2 mm (1 mm) are rejected to suppress muons from cosmic rays. Muon candidates are also required to satisfy “medium” quality criteria [68] and have $|\eta| < 2.5$. All electron and muon candidates must have $p_T > 10$ GeV. Lepton candidates remaining after resolving overlaps with baseline jets (see next paragraph) are called “baseline” leptons. In the control and signal regions where lepton identification is required, “signal” leptons are chosen from the baseline set with $p_T > 27$ GeV to ensure full efficiency of the trigger and are required to be isolated from other activity in the detector using a criterion designed to accept at least 95% of leptons from $Z$ boson decays as detailed in ref. [69]. The angular separation between the lepton and the $b$-jet arising from a semi-leptonically decaying top quark narrows as the top quark’s $p_T$ increases. This increased collimation is accounted for by varying the radius of the isolation cone as $\max(0.2, 10 \text{ GeV}/p_{T}^{\text{lep}})$, where $p_{T}^{\text{lep}}$ is the
lepton $p_T$. Signal electrons are further required to satisfy “tight” quality criteria. Electrons (muons) are matched to the primary vertex by requiring the transverse impact parameter ($d_0$) to satisfy $|d_0|/\sigma(d_0) < 5$ (3), and the longitudinal impact parameter ($z_0$) to satisfy $|z_0\sin\theta| < 0.5$ mm for both the electrons and muons. The MC events are corrected to account for differences in the lepton trigger, reconstruction and identification efficiencies between data and MC simulation.

The sequence to resolve overlapping electrons, muons and jets begins by removing electron candidates sharing an inner detector track with a muon candidate. Next, jet candidates within $\Delta R = \sqrt{(\Delta y)^2 + (\Delta \phi)^2} = 0.2$ of an electron candidate are discarded, unless the jet is $b$-tagged, in which case the electron is discarded since it is likely to originate from a semileptonic $b$-hadron decay. Electrons are discarded if they lie within $\Delta R = 0.4$ of a jet. Muons with $p_T$ below (above) 50 GeV are discarded if they lie within $\Delta R = 0.4$ ($\Delta R = 0.04 + 10$ GeV/$p_T$) of any remaining jet, except for the case where the number of tracks associated with the jet is less than three.

The missing transverse momentum is defined as the negative vector sum of the $p_T$ of all selected and calibrated physics objects (electrons, muons and jets) in the event, with an extra term added to account for soft energy in the event which is not associated with any of the selected objects. This soft term is calculated from inner detector tracks with $p_T$ above 0.4 GeV matched to the primary vertex to make it more robust against pile-up contamination [70, 71].

Reconstructed photons are not used in the main signal event selections but are selected in the regions employed in one of the alternative methods used to estimate the $Z^{\pm}$+jets background, as explained in section 6. Photon candidates are required to have $p_T > 145$ GeV and $|\eta| < 2.37$, whilst being outside the transition region $1.37 < |\eta| < 1.52$, to satisfy the tight photon shower shape and electron rejection criteria [72], and to be isolated.

5 Event selection

Two sets of signal regions (SRs) are defined and optimized to target different third-generation squark decay modes and mass hierarchies of the particles involved. The zero-lepton channel SRs (b0L) are designed to maximize the efficiency to retain bottom-squark pair production events where $\tilde{b}_1 \rightarrow b \tilde{\chi}_1^0$. The one-lepton channel selections (b1L) target SUSY models where bottom squarks decay with a significant branching ratio as $\tilde{b}_1 \rightarrow t \tilde{\chi}_1^\pm$ and the lightest chargino is almost degenerate with the lightest neutralino. With these assumptions, the final decay products of the off-shell $W$ boson from $\tilde{\chi}_1^\pm \rightarrow \tilde{\chi}_1^0 W^*$ are too soft to be detected. If the branching ratios of the two competing decay modes ($b \tilde{\chi}_1^0, t \tilde{\chi}_1^\pm$) are around 50%, the final state for the largest fraction of signal events is characterized by the presence of a top quark, a bottom quark, and neutralinos escaping the detector. Similarly, $\tilde{t}_1$ pair production can lead to an equivalent final state if the $\tilde{t}_1 \rightarrow t \tilde{\chi}_1^0$ and $\tilde{t}_1 \rightarrow b \tilde{\chi}_1^\pm$ decay modes compete.

5.1 Discriminating variables

Several kinematic variables and angular correlations, built from the physics objects defined in the previous section, are employed to discriminate SUSY from SM background events.
and are reported below. In the following, signal jets are used and are ordered according to decreasing $p_T$.

- $\Delta \phi_{\text{min}}$, $\min[\Delta \phi(\text{jet}_{1-4}, E_T^{\text{miss}})]$, $\min[\Delta \phi(\text{jet}_{1-2}, E_T^{\text{miss}})]$: these variables are the minimum $\Delta \phi$ between any of the leading jets and the missing transverse momentum vector. The background from multijet processes is characterized by small values of this variable. Depending on the signal regions, all, four or two jets are used.

- $H_T$: this is defined as the scalar sum of the $p_T$ of all jets in the event
  \[
  H_T = \sum_i (p_T^{\text{jet}})_i,
  \]
  where the number of jets involved depends on the signal region. In addition, the modified form of $H_T$, referred to as the $H_{T,4}$ variable, is used to reject events with extra-jet activity in signal regions targeting models characterized by small mass-splitting between the bottom squark and the neutralino. In $H_{T,4}$ the sum starts with the fourth jet (if any).

- $m_{\text{eff}}$: this is defined as the scalar sum of the $p_T$ of the jets and the $E_T^{\text{miss}}$, i.e.:
  \[
  m_{\text{eff}} = \sum_i (p_T^{\text{jet}})_i + E_T^{\text{miss}}.
  \]
  The $m_{\text{eff}}$ observable is correlated with the mass of the pair-produced SUSY particles and is employed as a discriminating variable in some of the zero-lepton and one-lepton channel selections, as well as in the computation of other composite observables.

- $E_T^{\text{miss}}/m_{\text{eff}}, E_T^{\text{miss}}/\sqrt{H_T}$: the first ratio is the $E_T^{\text{miss}}$ divided by the $m_{\text{eff}}$, while the second emulates the global $E_T^{\text{miss}}$ significance, given that the $E_T^{\text{miss}}$ resolution scales approximately with the square root of the total hadronic energy in the event. Events with low values for these variables are rejected as it is most probable that $E_T^{\text{miss}}$ arises from jets mismeasurements, caused by instrumental and resolution effects.

- $m_{jj}$: this variable is calculated as the invariant mass of the leading two jets. In events where at least one of the leading jets is $b$-tagged, this variable aids in reducing the contamination from $t \bar{t}$ events. It is referred to as $m_{bb}$ for events where the two leading jets are $b$-tagged.

- $m_T$: the event transverse mass $m_T$ is defined as
  \[
  m_T = \sqrt{-2p_T^{\text{lep}} E_T^{\text{miss}} - 2p_T^{\text{lep}} \cdot p_T^{\text{miss}}}
  \]
  and is used in the one-lepton control and signal regions to reduce the $W+\text{jets}$ and $t \bar{t}$ backgrounds.

- $m_{bl}^{\text{min}}$: the minimum invariant mass of the lepton and one of the two $b$-jets is defined as:
  \[
  m_{bl}^{\text{min}} = \min_{i=1,2} (m_{bl_i}).
  \]
  This variable is bound from above by $\sqrt{m_T^2 - m_W^2}$ for $t \bar{t}$ production, and it is used to distinguish $t \bar{t}$ contributions from $Wt$-channel single-top-quark events in the one-lepton control regions.
Contransverse mass ($m_{CT}$) [73]: this is the main discriminating variable in some of the zero-lepton channel signal regions [74]. It is used to measure the masses of pair-produced semi-invisibly decaying heavy particles. For identical decays of two heavy particles (e.g. the bottom squarks decaying exclusively as $\tilde{b}_1 \to b \tilde{\chi}_1^0$) into two visible particles $v_1$ and $v_2$ (the $b$-quarks), and two invisible particles $X_1$ and $X_2$ (the $\tilde{\chi}_1^0$ for the signal), $m_{CT}$ is defined as

$$m_{CT}^2(v_1, v_2) = [E_T(v_1) + E_T(v_2)]^2 - [p_T(v_1) - p_T(v_2)]^2,$$

with $E_T = \sqrt{p_T^2 + m^2}$, and it has a kinematical endpoint at $m_{CT}^{\text{max}} = (m_i^2 - m_X^2)/m_i$ where $i$ is the initially pair-produced particle. This variable is effective in suppressing the top-quark pair production background ($i = t, X = W$), for which the endpoint is at 135 GeV.

$m_{T}^\text{min}(\text{jet}_{1-4}, E_T^\text{miss})$: this is the minimum of the transverse masses calculated using any of the leading four jets and the $E_T^\text{miss}$ in the event. For signal scenarios with low values of $m_{CT}^{\text{max}}$, this kinematic variable is an alternative discriminating variable to reduce the $t\bar{t}$ background.

$am_{T2}$: the asymmetric transverse mass [75, 76] is a kinematic variable which can be used to separate processes in which two decays giving missing transverse momentum occur, and it is the main discriminating observable in the one-lepton channel signal regions. The $am_{T2}$ definition is based on the transverse mass ($m_{T2}$) [77]:

$$m_{T2}^2(\chi) = \min_{q_T^{(i)} + q_T^{(2)} = p_T^{\text{miss}}} \left\{ \max\left\{ m_{T2}^2(p_T(v_1), q_T^{(1)}; \chi), m_{T2}^2(p_T(v_2), q_T^{(2)}; \chi) \right\} \right\},$$

where $p_T(v_i)$ are reconstructed transverse momenta vectors and $q_T^{(i)}$ represent the missing transverse momenta from the two decays, with a total missing transverse momentum, $p_T^{\text{miss}}$; $\chi$ is a free parameter representing the unknown mass of the invisible particles — here assumed to be zero. The $a$ in $am_{T2}$ indicates that the two visible decay legs are asymmetric, i.e. not composed of the same particles.

In the case of events with one lepton (electron or muon) and two $b$-jets, the $m_{T2}$ variable is calculated for different values of $p_T(v_1)$ and $p_T(v_2)$, by grouping the lepton and the two $b$-jets into two visible objects $v_1$ and $v_2$. The lepton needs to be paired with one of the two $b$-jets and the choice is driven by the value of $m_{b\ell}(n)$ — the invariant mass of the $n^{th}$ $b$-tagged jet and the lepton. If the two particles are correctly associated, this value has an upper bound given by the top quark mass. The value of $am_{T2}$ is thus computed accordingly:

- If $m_{b\ell}(1)$ and $m_{b\ell}(2)$ are both $> 170$ GeV, neither of the two associations is compatible with the $b$-jet and the lepton originating from a top decay, so the event is rejected since all control, validation and signal regions require the smaller value of $m_{b\ell}$ to be $< 170$ GeV.
If \( m_{b'}(1) \) is < 170 GeV and \( m_{b'}(2) \) is > 170 GeV, \( m_{T2} \) is calculated with \( v_1 = b_1 + \ell \) and \( v_2 = b_2 \). This is done because only the first pairing is compatible with a top quark decay.

- Similarly, if \( m_{b'}(1) \) is > 170 GeV and \( m_{b'}(2) \) is < 170 GeV, \( m_{T2} \) is calculated with \( v_1 = b_1 \) and \( v_2 = b_2 + \ell \).

- If \( m_{b'}(1) \) and \( m_{b'}(2) \) are both < 170 GeV, \( m_{T2} \) is calculated in both configurations and its value is taken to be the smaller of the two. This must be done because, according to the \( m_{b'} \) check, both pairings would be acceptable.

\[ \mathcal{A} : \text{this is the } p_T \text{ asymmetry of the leading two jets and is defined as:} \]

\[ \mathcal{A} = \frac{p_T(j_1) - p_T(j_2)}{p_T(j_1) + p_T(j_2)}. \]

The \( \mathcal{A} \) variable is employed in scenarios where the mass-splitting between the bottom squark and the neutralino is small (< 20 GeV) and the selection exploits the presence of a high-momentum jet from initial-state radiation (ISR).

5.2 Zero-lepton channel selections

The selection criteria for the zero-lepton channel SRs are summarized in table 1 and have the main requirement of no baseline leptons with \( p_T > 10 \) GeV and two \( b \)-tagged jets. To exploit the kinematic properties over the large range of \( \tilde{b}_1 \) and \( \tilde{\chi}_1^0 \) masses explored, three sets of SRs are defined.

The b0L-SRA regions are optimized to be sensitive to models with large mass-splitting between the \( \tilde{b}_1 \) and the \( \tilde{\chi}_1^0 \), \( \Delta m(\tilde{b}_1, \tilde{\chi}_1^0) > 250 \) GeV. Incremental thresholds are imposed on the main discriminating variable, \( m_{CT} \), resulting in three overlapping regions (\( m_{CT} > 350, 450 \), and 550 GeV). Only events with \( E_T^{\text{miss}} > 250 \) GeV are retained to ensure full efficiency of the trigger and comply with the expected signal topology. The two leading jets are required to be \( b \)-tagged whilst contamination from backgrounds with high jet multiplicity, particularly \( t\bar{t} \) production, is suppressed by vetoing events with a fourth jet with \( p_T > 50 \) GeV. To discriminate against multijet background, events where \( E_T^{\text{miss}} \) is aligned with a jet in the transverse plane are rejected by requiring \( \min(\Delta\phi(jet_{1-4}, E_T^{\text{miss}})) > 0.4 \), and \( E_T^{\text{miss}}/m_{\text{eff}} > 0.25 \). A selection on the invariant mass of the two \( b \)-jets \( (m_{b\bar{b}} > 200 \) GeV) is applied to further enhance the signal yield over the SM background contributions.

The b0L-SRB region targets intermediate mass-splitting between \( \tilde{b}_1 \) and \( \tilde{\chi}_1^0 \), 50 < \( \Delta m(\tilde{b}_1, \tilde{\chi}_1^0) < 250 \) GeV. In these scenarios, the selections based on the \( m_{CT} \) and \( m_{b\bar{b}} \) variables are no longer effective and the variable \( m_{T2}^{\text{min}}(\text{jet}_{1-4}, E_T^{\text{miss}}) \) is employed to reduce SM background contributions from \( t\bar{t} \) production, with events selected if \( m_{T2}^{\text{min}}(\text{jet}_{1-4}, E_T^{\text{miss}}) > 250 \) GeV. No more than four signal jets are allowed, to reduce additional hadronic activity in the selected events. As opposed to the b0L-SRA criteria, no veto based on the fourth jet \( p_T \) is applied. A series of selections on the azimuthal angle between the two \( b \)-tagged jets and the \( E_T^{\text{miss}} \) are implemented (\( |\Delta\phi(b_1, E_T^{\text{miss}})| < 2.0 \) and \( |\Delta\phi(b_2, E_T^{\text{miss}})| < 2.5 \)) to reduce \( Z + \text{jets} \) background events.
Table 1. Summary of the event selection in each signal region for the zero-lepton channel. For SRA, the “x” denotes the $m_{CT}$ selection used. The term lepton is used in the table to refer to baseline electrons and muons. Jets ($j_1$, $j_2$, $j_3$, $j_4$ and $j_5$) are labelled with an index corresponding to their decreasing order in $p_T$.

Finally, the b0L-SRC region targets events where a bottom squark pair is produced in association with a jet from ISR. This selection provides sensitivity to models with a small mass difference between $\tilde{b}_1$ and $\tilde{b}_1$ ($\Delta m(\tilde{b}_1, \tilde{b}_1) < 50$ GeV), such that a boosted bottom squark pair would satisfy the trigger requirements. To efficiently suppress $t\bar{t}$ and $W$+jets backgrounds, events are selected with one high-$p_T$ non-$b$-tagged jet and $E_T^{miss} > 500$ GeV such that $\Delta \phi(j_1, E_T^{miss}) > 2.5$. Stringent requirements on the minimum azimuthal angle between the jets and $E_T^{miss}$ are not suited for these scenarios where $b$-jets have softer momenta and are possibly aligned with $E_T^{miss}$. A large asymmetry $A$ is required to reduce the multijet background while loosening the selection on the minimum azimuthal angle between the jets and $E_T^{miss}$ to min\(\phi(jet_1-4, E_T^{miss}) > 0.2\), and relaxing the $p_T$ threshold on signal jets to 20 GeV.

5.3 One-lepton channel selections

The selection criteria for the one-lepton channel SRs are summarized in table 2. Events are required to have exactly one signal electron or muon and no additional baseline leptons, two $b$-tagged jets and a large $E_T^{miss}$. Similarly to the zero-lepton channel, three sets of SRs are defined to maximize the sensitivity depending on the mass hierarchy between $\tilde{b}_1(t_1)$ and $\tilde{\chi}_1^0$.

</table>

Table 2. Summary of the event selection in each signal region for the one-lepton channel. For SRA, the “x” denotes the $m_{\text{eff}}$ selection used. The term lepton is used in the table to refer to signal electrons and muons. Jets ($j_1, j_2$) are labelled with an index corresponding to their decreasing order in $p_T$.

The b1L-SRA regions are optimized for models with large $\Delta m(\tilde{b}_1, \tilde{\chi}^0_1)$: events are required to have large $E_T^{\text{miss}}$ and $E_T^{\text{miss}}/\sqrt{H_T}$ and $\Delta \phi_{\text{min}}^{j}$ above 0.4 to reduce the multijet background contributions to negligible levels. Requirements on the $m_T$ and $a m_{T2}$ variables to be above 140 GeV and 250 GeV, respectively, are set to reject $W$+jets and $t\bar{t}$ events whilst the selection on the invariant mass of the two $b$-jets ($m_{bb} > 200$ GeV) is applied to further enhance the signal yield over the SM background contributions. Two incremental thresholds are finally imposed on $m_{\text{eff}}$ (600 and 750 GeV) to define two overlapping signal regions.

The b1L-SRB region is designed to be sensitive to compressed mass spectra, hence low $m_{bb}$ is expected, and the selections on the $m_T$ and $a m_{T2}$ variables must be relaxed to avoid loss of signal events. The $\min[m_T(b\text{-jet}, E_T^{\text{miss}})]$ is employed to discriminate signal from $t\bar{t}$ events, which is the dominant SM background contribution.

A third region, referred to as b1L-SRA300-2j, is defined similarly to the b1L-SRAs but requiring no extra jets beside the two $b$-jets and $m_{\text{eff}}$ above 300 GeV. Such a selection also targets SUSY models characterized by compressed mass spectra. It is kinematically similar to the signal region in the Run-1 analysis [20] with a veto requirement on the number of jets with $p_T > 50$ GeV.

6 Background estimation

Monte Carlo simulation is used to estimate the background yield in the signal regions. The MC prediction for the major backgrounds is normalized to data in control regions.
(CR) constructed to enhance a particular background and to be kinematically similar but mutually exclusive to the signal regions. The control regions are defined by explicitly requiring the presence of one or two leptons (electrons or muons) in the final state together with further selection criteria similar to those of the corresponding signal region. To ensure that the b0L and b1L analyses can be statistically combined, the CRs associated with b0L and b1L SRs are mutually exclusive, with the exception of the single-top CR, where the same CR is used for both channels.

The expected SM backgrounds are determined separately for each SR with a profile likelihood fit [78], referred to as the background-only fit. The fit uses as a constraint the observed event yields in a set of associated CRs to adjust the normalization of the main backgrounds, assuming that no signal is present. The inputs to the fit for each SR include the number of events observed in its associated CRs and the number of events predicted by simulation in each region for all background processes. The latter are described by Poisson statistics. The systematic uncertainties in the expected values are included in the fit as nuisance parameters. They are constrained by Gaussian distributions with widths corresponding to the sizes of the uncertainties and are treated as correlated, when appropriate, between the various regions. The product of the various probability density functions forms the likelihood, which the fit maximizes by adjusting the background normalization and the nuisance parameters. Finally, the reliability of the MC extrapolation of the SM background estimate outside of the control regions is evaluated in several validation regions (VRs).

### 6.1 Background estimation in the zero-lepton signal regions

The main SM background in the b0L signal regions is from the production of $Z$+jets followed by invisible decays of the $Z$ boson. The production of top quark pairs, single top quarks and $W$+jets also results in important backgrounds, with their relative contributions depending on the specific SR considered. Full details of the CR definitions are given in tables 3 and 4.

Three same-flavour opposite-sign (SFOS) two-lepton (electron or muon) control regions with dilepton invariant mass near the $Z$ boson mass ($76 < m_{\ell\ell} < 106 \text{ GeV}$) and two $b$-tagged jets provide data samples dominated by $Z$ boson production. Signal leptons are considered, with the threshold for the second lepton $p_T$ loosened to 20 GeV. For these control regions, labelled in the following as b0L-CRzA, b0L-CRzB and b0L-CRzC, the $p_T$ of the leptons is added vectorially to the $E_T^{\text{miss}}$ to mimic the expected missing transverse momentum spectrum of $Z \rightarrow \nu\bar{\nu}$ events, and is indicated in the following as $E_T^{\text{miss,cor}}$ (lepton corrected). In addition, a selection is applied to the uncorrected $E_T^{\text{miss}}$ of the event, in order to further enhance the $Z$ boson contribution.

Events with one charged lepton in the final state are used to define control regions dominated by $W$+jets and top quark production by requiring either one or two $b$-tagged jets, respectively. Selections on the variable $m_T$ are used to ensure that the lepton originates from a $W$ decay. For the CRs corresponding to b0L-SRA, the contribution from $t\bar{t}$ and single top quark production are separated by applying the selection $m_{bb} < 200 \text{ GeV}$ and $m_{bb} > 200 \text{ GeV}$, respectively. To further enhance the single-top-quark contribution, a selection on the minimum invariant mass of the lepton and one of the $b$-jets, $m_{bl}^{\text{min}} >$
Table 3. Summary of the event selection in each control region corresponding to b0L-SRA and b0L-SRB. The term lepton is used in the table to refer to signal electrons and muons. Jets ($j_1, j_2, j_3$ and $j_4$) and leptons ($\ell_1$ and $\ell_2$) are labelled with an index corresponding to their decreasing order in $p_T$.

</table>
170 GeV is applied. For the CRs corresponding to b0L-SRB, selections on the azimuthal angle between the $b$-jets and the $E_{T}^{\text{miss}}$ value are applied to enhance the $t\bar{t}$ and $W^{+}\text{jets}$ contributions, while the single-top-quark background is estimated from MC simulation. The CRs corresponding to the b0L-SRC are defined with one or two $b$-jets to enhance the $t\bar{t}$ and $W^{+}\text{jets}$ contributions, respectively. Finally, the single top quark production is estimated using the MC normalization.

The contributions from dibosons ($WW, WZ, ZZ$), $t\bar{t}$ production associated with $W$ and $Z$ bosons, and other rare backgrounds are estimated from MC simulation for both the signal and the control regions and included in the fit procedure, and are allowed to vary within their normalization uncertainty. The background from multijet production is estimated from data using a procedure described in detail in ref. [79] and modified to account for the heavy flavour of the jets. The contribution from multijet production in all regions is found to be negligible.

In total, four CRs are defined for the b0L-SRA to estimate the contributions from $W^{+}\text{jets}$, $Z^{+}\text{jets}$, $t\bar{t}$ and single top quark production independently, while three CRs are defined for each of the b0L-SRB and b0L-SRC to estimate $W^{+}\text{jets}$, $Z^{+}\text{jets}$ and $t\bar{t}$. The $E_{T}^{\text{miss}}$ distribution in b0L-CRwA and b0L-CRzC is shown in figures 2a and 2b, where good agreement with the SM prediction is achieved after the background-only fit. The yields in all these CRs are shown in figure 3 and compared to the MC predictions before the likelihood fit is performed, including only the statistical uncertainty of the MC samples. The bottom panel shows the value of the normalization factors, $\mu$, used for each of the backgrounds fitted and given taking into account statistical and detector-related systematic uncertainties.

As a further validation, two alternative methods are used to estimate the $Z^{+}\text{jets}$ contribution. The first method exploits the similarity of the $Z^{+}\text{jets}$ and $\gamma^{+}\text{jets}$ processes [79]. For a photon with $p_{T}$ significantly larger than the mass of the $Z$ boson, the kinematics of $\gamma^{+}\text{jets}$ events strongly resemble those of $Z^{+}\text{jets}$ events. A set of dedicated control regions is defined by requiring one isolated photon with $p_{T} > 145$ GeV. The $p_{T}$ of the photon is vectorially added to the $p_{T}^{\text{miss}}$, and the magnitude of this sum is used to replace the $E_{T}^{\text{miss}}$-based selections. The yields are then propagated to the SRs using a reweighting factor derived using the MC simulation. This factor takes into account the different kinematics of the two processes and residual effects arising from the different geometrical acceptance and reconstruction efficiency for photons. In the second alternative method, applied to b0L-SRA only, the MC simulation is used to verify that the shape of the $m_{CT}$ distribution for events with no $b$-tagged jets is compatible with the shape of the $m_{CT}$ distribution for events where two $b$-tagged jets are present. A new highly populated $Z^{+}\text{jets}$ CR is defined, selecting $Z \to \ell\ell$ events with no $b$-tagged jets. The $m_{CT}$ distribution in this CR is constructed using the two leading jets and is used to estimate the shape of the $m_{CT}$ distribution in the b0L-SRA, whilst the normalization in SRA is rescaled based on the ratio in data of $Z \to \ell\ell$ events with no $b$-tagged jets to events with two $b$-tagged jets. Additional MC-based corrections are applied to take into account the two-lepton selection in this CR. The two alternative methods are in agreement within uncertainties with the estimates obtained with the profile likelihood fit to the control regions. Experimental and theoretical
systematic uncertainties in the estimates from the nominal and alternative methods are taken into account (see section 7).

6.2 Background estimation in the one-lepton signal regions

The main SM background in the b1L signal regions is the production of $t\bar{t}$ and single-top-quark events in the $Wt$ channel. Two control regions (b1L-CRttA and b1L-CRttB) where the $t\bar{t}$ production is enhanced are defined by inverting the $m_{T2}$ selection. In the case of b1L-CRttA the $m_{bb}$ selection is also inverted, while for b1L-CRttB the $\min[m_T(b\text{-jet}, E_T^{\text{miss}})]$ requirement is inverted. To allow a statistical combination of the results from the b0L-SRA and b1L-SRA regions the corresponding $t\bar{t}$ CRs are defined to be orthogonal via the $m_{CT}$ selection. The single-top-quark contribution is estimated with the same CR employed by the b0L analysis. In the case of b1L-SRB the production of $W+$jets is no longer negligible, and is estimated by using a dedicated control region b1L-CRWB, where only one $b$-tagged jet is required. In total, two CRs are used to estimate the event yields in b1L-SRA and three CRs to estimate the yields in b1L-SRB. Full details of the CR selections are given in table 5. The distribution of $m_{bb}$ in b1L-CRstA and of $m_T$ in b1L-CRttB are presented in figures 2c and 2d to show the level of agreement achieved after the background-only fit.

The yields in all these CRs are also shown in figure 3 and compared to the direct MC prediction before the likelihood fit is performed. The normalization parameters reported for each SR and SM background process include the statistical and detector-related systematic uncertainties. The decrease of the $\mu_{t\bar{t}}$ parameter from SRA to SRC is related to mismodelling in the description of $t\bar{t}$ processes by POWHEG+PYTHIA 6 MC samples. Previous analyses [80] also found normalization factors considerably smaller than unity for $t\bar{t}$ background processes in similar regions of phase space. The $W+$jets and $Z+$jets normalization factors are larger than unity. This is possibly related to the fact that in the default SHERPA 2.2.1 the heavy-flavour production fractions are not consistent with the measured values [81].

6.3 Validation regions

The results of the background-only fit to the CRs are extrapolated to a set of VRs defined to be similar to the SRs, with some of the selection criteria modified to enhance the background contribution, while maintaining a small signal contribution. For each SR, one or more VRs are defined starting from the SR definition and inverting or changing some of the selections as summarized in table 6.

The number of events predicted by the background-only fit is compared to the data in the upper panel of figure 4. The pull, defined by the difference between the observed number of events ($n_{\text{obs}}$) and the predicted background yield ($n_{\text{pred}}$) divided by the total uncertainty ($\sigma_{\text{tot}}$), is shown for each region in the lower panel. No evidence of significant background mismodelling is observed in the VRs.
Table 5. Summary of the event selection in each control region corresponding to the b1L signal regions. The term lepton is used in the table to refer to signal electrons and muons. Jets (\(j_1, j_2, j_3\) and \(j_4\)) are labelled with an index corresponding to their decreasing order in \(p_T\).

Table 6. Summary of the VRs used in the analysis. Each VR (left column) corresponds to a SR (middle column) defined in tables 1 and 2, with a few selection requirements changed (right column) to ensure the selection has low efficiency for the expected signal.
Figure 2. Example kinematic distributions in some of the control regions. (a) $E^{\text{miss}}_T$ in b0L-CRwA, (b) $E^{\text{miss,cor}}_T$ in b0L-CRzC, (c) $m_{bb}$ in b1L-CRstA and (d) $m_T$ in b1L-CRttB. In all distributions the MC normalization is rescaled using the results from the background-only fit, showing good agreement between data and the predicted SM shapes. The contributions from diboson, multijet and rare backgrounds are collectively called “Others”. The shaded-grey band shows the detector-related systematic uncertainties and the statistical uncertainties of the MC samples as detailed in section 7 and the last bin includes overflow events.

7 Systematic uncertainties

Several sources of experimental and theoretical systematic uncertainty in the signal and background estimates are considered in these analyses. Their impact is reduced through the normalization of the dominant backgrounds in the control regions defined with kinematic selections resembling those of the corresponding signal region (see section 6). Experimental and theoretical uncertainties are included as nuisance parameters with Gaussian constraints in the likelihood fits, taking into account correlations between different regions. Uncertainties due to the numbers of events in the CRs are also introduced in the fit for each region. The dominant contributions are summarized in table 7.
Figure 3. Data and MC predictions for all CRs associated with all b0L and b1L SRs before the likelihood fit, as well as the results obtained by the likelihood fit. In the top panel the normalization of the backgrounds is obtained from MC simulation and is the input value to the fit. The contributions from diboson, multijet and rare backgrounds are collectively called “Others”. The panels at the bottom show the ratio of the observed events in each CR to the MC estimate, and the value of the normalization factors (μ) obtained for each of the backgrounds fitted. The uncertainty band around the MC prediction includes only the statistical uncertainty of the MC samples. The normalization factors μ are presented for each region and SM background process and take into account statistical and detector-related systematic uncertainties.

Table 7. Summary of the dominant experimental and theoretical uncertainties for each signal region in zero-lepton and one-lepton channels. Uncertainties are quoted as relative to the total SM background predictions, with a range indicated for the three b0L-SRAs and the two b1L-SRAs. For theoretical modelling, uncertainties per dominant SM background process are quoted. The individual uncertainties can be correlated, and do not necessarily add in quadrature to the total background uncertainty.
Figure 4. Results of the likelihood fit extrapolated to the VRs associated with the b0L and b1L analyses. The normalization of the backgrounds is obtained from the fit to the CRs. The upper panel shows the observed number of events and the predicted background yield. The contributions from diboson, multijet and rare backgrounds are collectively called “Others”. All uncertainties defined in section 7 are included in the uncertainty band. The lower panel shows the pulls in each VR, where $\sigma_{\text{tot}}$ is the error on the background estimation as a sum in quadrature of the systematic uncertainty and the statistical uncertainty on the estimate.

The dominant detector-related systematic effects are due to the uncertainties in the jet energy scale (JES) [59] and resolution (JER) [82], and in the $b$-tagging efficiency and mis-tagging rates. The latter are estimated by varying the $\eta$, $p_T$- and flavour-dependent scale factors applied to each jet in the simulation within a range that reflects the systematic uncertainty in the measured tagging efficiency and mis-tag rates in 13 TeV data. The uncertainties associated with lepton and photon reconstruction and energy measurements are also considered but have a negligible impact on the final results. Lepton, photon and jet-related uncertainties are propagated to the $E_{\text{miss}}$ calculation, and additional uncertainties are included in the energy scale and resolution of the soft term.

Uncertainties in the modelling of the SM background processes from MC simulation and their theoretical cross-section uncertainties are also taken into account. The dominant uncertainty arises from $Z$+jets MC modelling for b0L-SRs and $t\bar{t}$ and single-top modelling (collectively referred to as “Top production” in table 7) for b1L-SRs. The $Z$+jets (as well as $W$+jets) modelling uncertainties are estimated by considering different merging (CKKW-L) and resummation scales using alternative samples, PDF variations from the NNPDF30NNLO replicas [46], as well as an envelope formed from seven-point scale variations of the renormalization and factorization scales. The various components are added in quadrature. A 40% uncertainty [83] is assigned to the heavy-flavour jet content in $W$+jets background, which is estimated from MC simulation in the one-lepton channel control re-
regions. For b0L-SRA, b0L-SRC and b1L-SRB the uncertainty accounts for the different requirements on $b$-jets between the signal regions and the corresponding control regions.

Theoretical and modelling uncertainties of the top quark pair and single-top-quark ($Wt$) backgrounds are computed as the difference between the prediction from nominal samples and those from additional samples differing in generator or parameter settings. Hadronization and PS uncertainties are estimated using samples generated using POWHEG-Box v2 and showered by HERWIG++ v2.7.1 [84] with the UEEE5 [85] underlying-event tune. Uncertainties related to initial- and final-state radiation modelling, PS tune and (for $t\bar{t}$ only) choice of $h_{\text{damp}}$ parameter in POWHEG-Box v2 are estimated using alternative settings of the event generators. Finally, an alternative generator MADGRAPH5_aMC@NLO with showering by HERWIG++ v2.7.1 is used to estimate the event generator uncertainties. One additional uncertainty stems from the modelling of the interference between the $t\bar{t}$ and $Wt$ processes at NLO. Predictions from an inclusive $WWbb$ sample generated at LO using MADGRAPH5_aMC@NLO are compared with the sum of the $t\bar{t}$ and $Wt$ predictions, and differences from the nominal predictions are taken as systematic uncertainties.

Uncertainties in backgrounds such as diboson and $ttV$ are also estimated by comparisons of the nominal sample with alternative samples differing in generator or parameter settings (POWHEG v2 with showering by PYTHIA v8.210 for dibosons; renormalization and factorization scale and A14 tune variations for $ttV$) and contribute less than 5% to the total uncertainty. The cross-sections used to normalize the MC yields to the highest order available are varied according to the scale uncertainty of the theoretical calculation. The cross-section uncertainties are 5% for $W$ boson, $Z$ boson and top quark pair production, 6% for dibosons, and 13% and 12% for $ttW$ and $ttZ$, respectively. Finally, a conservative 100% systematic uncertainty associated to the multijet background estimate is considered and found to have a negligible effect.

For the SUSY signal processes, both the experimental and theoretical uncertainties in the expected signal yield are considered. Experimental uncertainties are found to be between 15% and 30% across the $\tilde{b}_1-\tilde{\chi}^0_1$ mass plane for exclusive $\tilde{b}_1 \rightarrow b\tilde{\chi}^0_1$ decays and between 10% and 25% for models where bottom squarks decay with a significant branching ratio as $\tilde{b}_1 \rightarrow t\tilde{\chi}^\pm_1$, assuming the one-lepton channel selection. In all SRs, they are largely dominated by the uncertainty in the $b$-tagging efficiency. Theoretical uncertainties in the NLO+NLL cross-section are calculated for each SUSY signal scenario and are dominated by the uncertainties in the renormalization and factorization scales, followed by the uncertainty in the PDF. They vary between 15% and 25% for bottom squark masses in the range between 400 GeV and 1100 GeV. Additional uncertainties in the acceptance and efficiency due to the modelling of initial-state radiation and scale variations in SUSY signal MC samples are also taken into account and contribute up to about 10%.

8 Results and interpretation

Tables 8 and 9 report the observed number of events and the SM prediction after the background-only fit for each signal region in the zero-lepton and one-lepton channels, respectively. The background-only fit results are compared to the pre-fit predictions based
Table 8. Fit results in the b0L signal regions. The background normalization parameters are obtained from the fit in the control regions and are applied to the SRs. Smaller backgrounds such as diboson, tttV, multijet and rare processes are indicated as “Others”. The individual uncertainties, including statistical, detector-related and theoretical systematic components, are symmetrized and can be correlated. They do not necessarily add in quadrature to the total systematic uncertainty.

The results are translated into upper limits on contributions from physics beyond the SM (BSM) for each signal region. The CL$_s$ method [86, 87] is used to derive the confidence level of the exclusion; signal models with a CL$_s$ value below 0.05 are said to be excluded at 95% CL. The profile-likelihood-ratio test statistic is used to exclude the signal-plus-background hypothesis for specific signal models. $S^{95}_{\text{obs}}$ ($S^{95}_{\text{exp}}$) is the observed (expected) upper limit at 95% CL on the number of events from BSM phenomena for each signal region. These limits, when normalized by the integrated luminosity of the data sample, may be interpreted as upper limits on the visible cross-section of BSM physics, $\sigma_{\text{vis}}$, defined as the product of the production cross-section, the acceptance and the selection efficiency of a BSM signal. Table 10 summarizes $S^{95}_{\text{obs}}$, $S^{95}_{\text{exp}}$, and $\sigma_{\text{vis}}$ for all SRs, together with the $p_0$-values, which represent the probability of the SM background alone to fluctuate to the observed number of events or higher.

Table 10. Left to right: 95% CL upper limits on the visible cross-section ($\langle \epsilon A \sigma \rangle_{\text{obs}}^{95\%}$) and on the number of signal events ($S_{\text{obs}}^{95\%}$). The third column ($S_{\text{exp}}^{95\%}$) shows the 95% CL upper limit on the number of signal events, given the expected number (and ±1σ variations of the expected number) of background events. The last column reports the $p_0$-values and $Z$ (the number of equivalent Gaussian standard deviations). The maximum allowed $p_0$-value is truncated at 0.5.
Figure 5. Results of the likelihood fit extrapolated to the SRs associated with the b0L and b1L analyses. The normalization of the backgrounds is obtained from the fit to the CRs. The upper panel shows the observed number of events and the predicted background yields. The contributions from diboson, multijet and rare backgrounds are collectively called “Others”. All uncertainties defined in section 7 are included in the uncertainty band. The lower panel shows the pulls in each SR, where $\sigma_{\text{tot}}$ is the error on the background estimation as a sum in quadrature of the systematic uncertainty and the statistical uncertainty on the estimate.

Exclusion limits are obtained assuming two types of SUSY particle mass hierarchy such that the lightest bottom squark decays either exclusively via $\tilde{b}_1 \to b\tilde{\chi}_1^0$ or into multiple channels, $\tilde{b}_1 \to b\tilde{\chi}_1^0$ and $\tilde{b}_1 \to t\tilde{\chi}_1^\pm$, assuming a 50% branching ratio and $\Delta m(\tilde{\chi}_1^\pm, \tilde{\chi}_1^0) \sim 1$ GeV. The first set of scenarios is targeted by the zero-lepton channel SRs only. For models with mixed decays, the expected limits from the SRs are compared and the observed limits are obtained by statistically combining the most sensitive zero-lepton SR with the most sensitive one-lepton SR. In all cases, the fit procedure takes into account correlations in the yield predictions between control and signal regions due to common background normalization parameters and systematic uncertainties. The experimental systematic uncertainties in the signal are taken into account for this calculation and are assumed to be fully correlated with those in the SM background.

For the exclusive $\tilde{b}_1 \to b\tilde{\chi}_1^0$ decay mode, at each point of the parameter space the SR with the best expected sensitivity is used. Sensitivity to scenarios with the largest mass difference between the $\tilde{b}_1$ and the $\tilde{\chi}_1^0$ is achieved with the most stringent $m_{\tilde{c}_T}$ threshold (b0L-SRA550). Sensitivity to scenarios with intermediate and small mass differences is obtained with the dedicated b0L-SRB and b0L-SRC selections, respectively. For the mixed-decays scenarios, a statistical combination is computed with the results of the zero-lepton and one-lepton channels as explained above. A combined fit is performed simultaneously on the control and signal regions of the two analyses. The best sensitivity to regions of the
Figure 6. Distributions of (a) $m_{CT}$ in b0L-SRA, (b) $m_{T}(\text{jet}_{1-4}, E_{T}^{\text{miss}})$ in b0L-SRB, (c) $A$ in b0L-SRC, (d) $m_{bb}$ in b1L-SRA300-2j, (e) $m_{\text{eff}}$ in b1L-SRA, (f) $m_{T}$ in b1L-SRB. All selection criteria are applied, except the selection on the variable that is displayed in each of the plots. The arrows indicate the final selection applied in the signal regions. The shaded-grey band shows the detector-related systematic uncertainties and the statistical uncertainties on the MC samples. The SM backgrounds are normalized to the values determined in the $t\bar{t}$ channel. The contributions from diboson, multijet and rare backgrounds are collectively called “Others”. For illustration the distribution expected from selected signal models are overlaid. The last bin includes overflow events.
Figure 7. (a) Observed and expected exclusion contours at 95% CL, as well as $\pm 1\sigma$ variation of the expected limit, in the $\tilde{b}_1-\tilde{\chi}^0_1$ mass plane. The SR with the best expected sensitivity is adopted for each point of the parameter space. The yellow band around the expected limit (dashed line) shows the impact of the experimental and SM background theoretical uncertainties. The dotted lines show the impact on the observed limit of the variation of the nominal signal cross-section by $\pm 1\sigma$ of its theoretical uncertainties. (b) Same, for scenarios where multiple decay modes are considered for bottom squarks. The statistical combination of b0L-SRs and b1L-SRs is used in this case. In (b) differences between expected and observed contours around $m_{\tilde{b}_1}$ = 500 GeV arise from the one $\sigma$ level discrepancy between the data and the predicted SM background contributions in b0L-SRB and b1L-SRB.

(\tilde{b}_1, \tilde{\chi}^0_1) mass plane close to the kinematic boundaries is obtained with the combination of the b0L-SR450 and b1L-SRB regions whilst stringent constraints on models with large mass differences are achieved with the results from the combination of zero-lepton and one-lepton SRs with the most stringent $m_{CT}$ and $m_{eff}$ thresholds, respectively.

Figures 7a and 7b show the observed (solid line) and expected (dashed line) exclusion contours at 95% CL in the $\tilde{b}_1-\tilde{\chi}^0_1$ mass plane for the two types of SUSY scenarios considered. Bottom squark masses up to 950 (860) GeV are excluded for $\tilde{\chi}^0_1$ masses below 420 (250) GeV in models with exclusive (mixed) decay modes. Multiple-decay bottom squark models are phenomenologically equivalent to models characterized by the pair production of top squarks decaying as $\tilde{t}_1 \rightarrow t\tilde{\chi}^0_1$ and $\tilde{t}_1 \rightarrow b\tilde{\chi}^{\pm}_1$, with the same assumptions for the branching ratios and $\Delta m(\tilde{\chi}^{\pm}_1, \tilde{\chi}^0_1)$. Hence the results can be interpreted as exclusion limits on top squark masses.

9 Conclusion

The results of a search for pair production of bottom and top squarks are reported. The analysis uses 36.1 fb$^{-1}$ of $pp$ collisions at $\sqrt{s} =$ 13 TeV collected by the ATLAS experiment at the Large Hadron Collider in 2015 and 2016. Third-generation squarks are searched for in events containing large missing transverse momentum and jets, exactly two of which
are identified as $b$-jets. Selections are defined with either no charged leptons (electrons and muons) in the final state, or one charged lepton. Zero-lepton channel signal regions target $R$-parity-conserving models in which the $\tilde{b}_1$ is the lightest squark and is assumed to decay exclusively via $\tilde{b}_1 \rightarrow b\tilde{\chi}_1^0$, where $\tilde{\chi}_1^0$ is the lightest neutralino. One-lepton channel signal regions target models where bottom or top squarks are produced and can decay into multiple channels, $\tilde{b}_1 \rightarrow b\tilde{\chi}_1^0$ and $\tilde{b}_1 \rightarrow t\tilde{\chi}_1^\pm$, or $\tilde{t}_1 \rightarrow t\tilde{\chi}_1^0$ and $\tilde{t}_1 \rightarrow b\tilde{\chi}_1^\pm$, where $\tilde{\chi}_1^\pm$ is the lightest chargino and the mass difference $m_{\tilde{\chi}_1^\pm} - m_{\tilde{\chi}_1^0}$ is set to 1 GeV. No significant excess above the expected Standard Model background is found and exclusion limits at 95% confidence level are placed on the visible cross-section and on the mass of the bottom (or top) squark. Bottom squark masses up to 950 GeV are excluded for $\tilde{\chi}_1^0$ masses below 420 GeV in models with exclusive decay modes. Bottom or top squark masses up to 860 GeV are excluded for $\tilde{\chi}_1^0$ masses below 250 GeV in models with mixed decay modes with equal branching ratios. The results significantly improve upon previous Run-1 and Run-2 searches at the ATLAS experiment and strengthen the constraints on bottom and top squark masses.

Acknowledgments

We thank CERN for the very successful operation of the LHC, as well as the support staff from our institutions without whom ATLAS could not be operated efficiently.

We acknowledge the support of ANPCyT, Argentina; YerPhI, Armenia; ARC, Australia; BMWFW and FWF, Austria; ANAS, Azerbaijan; SSTC, Belarus; CNPq and FAPESP, Brazil; NSERC, NRC and CFI, Canada; CERN; CONICYT, Chile; CAS, MOST and NSFC, China; COLCIENCIAS, Colombia; MSMT CR, MPO CR and VSC CR, Czech Republic; DNRF and DNSRC, Denmark; IN2P3-CNRS, CEA-DSM/IRFU, France; SRNSF, Georgia; BMBF, HGF, and MPG, Germany; GSRT, Greece; RGC, Hong Kong SAR, China; ISF, I-CORE and Benoziyo Center, Israel; INFN, Italy; MEXT and JSPS, Japan; CNRST, Morocco; NWO, Netherlands; RCN, Norway; MNI SW and NCN, Poland; FCT, Portugal; MNE/IFA, Romania; MES of Russia and NRC KI, Russian Federation; JINR; MESTD, Serbia; MSSR, Slovakia; ARRS and MIZŠ, Slovenia; DST/NRF, South Africa; MINECO, Spain; SRC and Wallenberg Foundation, Sweden; SERI, SNSF and Cantons of Bern and Geneva, Switzerland; MOST, Taiwan; TAEK, Turkey; STFC, United Kingdom; DOE and NSF, United States of America. D.R. Tovey, 

[81] ATLAS collaboration, "Studies on top-quark Monte Carlo modelling with Sherpa and MG5\_aMC@NLO, ATL-PHYS-PUB-2017-007 (2017)."

Physics Division, Lawrence Berkeley National Laboratory and University of California, Berkeley CA, United States of America
Department of Physics, Humboldt University, Berlin, Germany
Albert Einstein Center for Fundamental Physics and Laboratory for High Energy Physics, University of Bern, Bern, Switzerland
School of Physics and Astronomy, University of Birmingham, Birmingham, United Kingdom
(a) Department of Physics, Bogazici University, Istanbul; (b) Department of Physics Engineering, Gaziantep University, Gaziantep; (d) Istanbul Bilgi University, Faculty of Engineering and Natural Sciences, Istanbul; (e) Bahcesehir University, Faculty of Engineering and Natural Sciences, Istanbul, Turkey
Centro de Investigaciones, Universidad Antonio Nariño, Bogota, Colombia
(a) INFN Sezione di Bologna; (b) Dipartimento di Fisica e Astronomia, Università di Bologna, Bologna, Italy
Department of Physics, Boston University, Boston MA, United States of America
Department of Physics, Brandeis University, Waltham MA, United States of America
(a) Universidade Federal do Rio De Janeiro COPPE/EE/IF, Rio de Janeiro; (b) Electrical Circuits Department, Federal University of Juiz de Fora (UFJF), Juiz de Fora; (c) Federal University of Sao Joao del Rei (UFSJ), Sao Joao del Rei; (d) Instituto de Fisica, Universidade de Sao Paulo, Sao Paulo, Brazil
Physics Department, Brookhaven National Laboratory, Upton NY, United States of America
(a) Transilvania University of Brasov, Brasov; (b) Horia Hulubei National Institute of Physics and Nuclear Engineering, Bucharest; (c) Department of Physics, Alexandru Ioan Cuza University of Iasi, Iasi; (d) National Institute for Research and Development of Isotopic and Molecular Technologies, Physics Department, Cluj Napoca; (e) University Politehnica Bucharest, Bucharest; (f) West University in Timisoara, Timisoara, Romania
Departamento de Fisica, Universidad de Buenos Aires, Buenos Aires, Argentina
Cavendish Laboratory, University of Cambridge, Cambridge, United Kingdom
Department of Physics, Carleton University, Ottawa ON, Canada
CERN, Geneva, Switzerland
Enrico Fermi Institute, University of Chicago, Chicago IL, United States of America
(a) Departamento de Física, Pontificia Universidad Católica de Chile, Santiago; (b) Departamento de Física, Universidad Técnica Federico Santa María, Valparaíso, Chile
(a) Institute of High Energy Physics, Chinese Academy of Sciences, Beijing; (b) Department of Physics, Nanjing University, Jiangsu; (c) Physics Department, Tsinghua University, Beijing 100084, China
(a) Department of Modern Physics and State Key Laboratory of Particle Detection and Electronics, University of Science and Technology of China, Anhui; (b) School of Physics, Shandong University, Shandong; (c) Department of Physics and Astronomy, Key Laboratory for Particle Physics, Astrophysics and Cosmology, Ministry of Education; Shanghai Key Laboratory for Particle Physics and Cosmology, Shanghai Jiao Tong University, Shanghai(also at PKU-CHEP), China
Université Clermont Auvergne, CNRS/IN2P3, LPC, Clermont-Ferrand, France
Nevis Laboratory, Columbia University, Irvington NY, United States of America
Niels Bohr Institute, University of Copenhagen, Kobenhavn, Denmark
(a) INFN Gruppo Collegato di Cosenza, Laboratori Nazionali di Frascati; (b) Dipartimento di Fisica, Università della Calabria, Rende, Italy
(a) AGH University of Science and Technology, Faculty of Physics and Applied Computer Science, Krakow; (b) Marian Smoluchowski Institute of Physics, Jagiellonian University, Krakow, Poland
Institute of Nuclear Physics Polish Academy of Sciences, Krakow, Poland
Physics Department, Southern Methodist University, Dallas TX, United States of America
Physics Department, University of Texas at Dallas, Richardson TX, United States of America
DESY, Hamburg and Zeuthen, Germany
Lehrstuhl für Experimentelle Physik IV, Technische Universität Dortmund, Dortmund, Germany
Institut für Kern- und Teilchenphysik, Technische Universität Dresden, Dresden, Germany
Department of Physics, Duke University, Durham NC, United States of America
SUPA - School of Physics and Astronomy, University of Edinburgh, Edinburgh, United Kingdom
INFN e Laboratori Nazionali di Frascati, Frascati, Italy
Fakultät für Mathematik und Physik, Albert-Ludwigs-Universität, Freiburg, Germany
Département de Physique Nucléaire et Corpusculaire, Université de Genève, Geneva, Switzerland
(a) INFN Sezione di Genova; (b) Dipartimento di Fisica, Università di Genova, Genova, Italy
E. Andronikashvili Institute of Physics, Iv. Javakhishvili Tbilisi State University, Tbilisi; (b) High Energy Physics Institute, Tbilisi State University, Tbilisi, Georgia
II Physikalisches Institut, Justus-Liebig-Universität Giessen, Giessen, Germany
SUPA - School of Physics and Astronomy, University of Glasgow, Glasgow, United Kingdom
II Physikalisches Institut, Georg-August-Universität, Göttingen, Germany
Laboratoire de Physique Subatomique et de Cosmologie, Université Grenoble-Alpes, CNRS/IN2P3, Grenoble, France
Laboratory for Particle Physics and Cosmology, Harvard University, Cambridge MA, United States of America
(a) Kirchhoff-Institut für Physik, Ruprecht-Karls-Universität Heidelberg, Heidelberg; (b) Physikalisches Institut, Ruprecht-Karls-Universität Heidelberg, Heidelberg, Germany
Faculty of Applied Information Science, Hiroshima Institute of Technology, Hiroshima, Japan
(a) Department of Physics, The Chinese University of Hong Kong, Shatin, N.T., Hong Kong; (b) Department of Physics and Institute for Advanced Study, The Hong Kong University of Science and Technology, Clear Water Bay, Kowloon, Hong Kong, China
Department of Physics, National Tsing Hua University, Hsinchu, Taiwan
Department of Physics, Indiana University, Bloomington IN, United States of America
Institut für Astro- und Teilchenphysik, Leopold-Franzens-Universität, Innsbruck, Austria
University of Iowa, Iowa City IA, United States of America
Department of Physics and Astronomy, Iowa State University, Ames IA, United States of America
Joint Institute for Nuclear Research, JINR Dubna, Dubna, Russia
KEK, High Energy Accelerator Research Organization, Tsukuba, Japan
Graduate School of Science, Kobe University, Kobe, Japan
Faculty of Science, Kyoto University, Kyoto, Japan
Kyoto University of Education, Kyoto, Japan
Research Center for Advanced Particle Physics and Department of Physics, Kyushu University, Fukuoka, Japan
(a) INFN Sezione di Lecce; (b) Dipartimento di Matematica e Fisica, Università del Salento, Lecce, Italy
Oliver Lodge Laboratory, University of Liverpool, Liverpool, United Kingdom
Department of Experimental Particle Physics, Jozef Stefan Institute and Department of Physics, University of Ljubljana, Ljubljana, Slovenia
School of Physics and Astronomy, Queen Mary University of London, London, United Kingdom
Department of Physics, Royal Holloway University of London, Surrey, United Kingdom
Department of Physics and Astronomy, University College London, London, United Kingdom
Louisiana Tech University, Ruston LA, United States of America
Laboratoire de Physique Nucléaire et de Hautes Energies, UPMC and Université Paris-Diderot and CNRS/IN2P3, Paris, France
Fysiska institutionen, Lunds universitet, Lund, Sweden
Departamento de Física Teórica C-15, Universidad Autónoma de Madrid, Madrid, Spain
Institut für Physik, Universität Mainz, Mainz, Germany
de Ciências, Universidade de Lisboa, Lisboa; (c) Department of Physics, University of Coimbra, Coimbra; (d) Centro de Física Nuclear da Universidade de Lisboa, Lisboa; (e) Departamento de Física, Universidade do Minho, Braga; (f) Departamento de Física Teórica y del Cosmos, Universidad de Granada, Granada; (g) Dep Física and CEFITEC of Faculdade de Ciências e Tecnologia, Universidade Nova de Lisboa, Caparica, Portugal

129 Institute of Physics, Academy of Sciences of the Czech Republic, Praha, Czech Republic
130 Czech Technical University in Prague, Praha, Czech Republic
131 Charles University, Faculty of Mathematics and Physics, Prague, Czech Republic
132 State Research Center Institute for High Energy Physics (Protvino), NRC KI, Russia
133 Particle Physics Department, Rutherford Appleton Laboratory, Didcot, United Kingdom
134 (a) INFN Sezione di Roma; (b) Dipartimento di Fisica, Sapienza Università di Roma, Roma, Italy
135 (a) INFN Sezione di Roma Tor Vergata; (b) Dipartimento di Fisica, Università di Roma Tor Vergata, Roma, Italy
136 (a) INFN Sezione di Roma Tre; (b) Dipartimento di Matematica e Fisica, Università Roma Tre, Roma, Italy
137 (a) Faculté des Sciences Ain Chock, Réseau Universitaire de Physique des Hautes Energies - Université Hassan II, Casablanca; (b) Centre National de l’Energie des Sciences Techniques Nucleaires, Rabat; (c) Faculté des Sciences Semlalia, Université Cadi Ayyad, LPHEA-Marrakech; (d) Faculté des Sciences, Université Mohamed Premier and LPTPM, Oujda; (e) Faculté des sciences, Université Mohammed V, Rabat, Morocco
138 DSM/IRFU (Institut de Recherches sur les Lois Fondamentales de l’Univers), CEA Saclay (Commissariat à l’Energie Atomique et aux Energies Alternatives), Gif-sur-Yvette, France
139 Santa Cruz Institute for Particle Physics, University of California Santa Cruz, Santa Cruz CA, United States of America
140 Department of Physics, University of Washington, Seattle WA, United States of America
141 Department of Physics and Astronomy, University of Sheffield, Sheffield, United Kingdom
142 Department of Physics, Shinshu University, Nagano, Japan
143 Department Physik, Universität Siegen, Siegen, Germany
144 Department of Physics, Simon Fraser University, Burnaby BC, Canada
145 SLAC National Accelerator Laboratory, Stanford CA, United States of America
146 (a) Faculty of Mathematics, Physics & Informatics, Comenius University, Bratislava; (b) Department of Subnuclear Physics, Institute of Experimental Physics of the Slovak Academy of Sciences, Kosice, Slovak Republic
147 (a) Department of Physics, University of Cape Town, Cape Town; (b) Department of Physics, University of Johannesburg, Johannesburg; (c) School of Physics, University of the Witwatersrand, Johannesburg, South Africa
148 (a) Department of Physics, Stockholm University; (b) The Oskar Klein Centre, Stockholm, Sweden
149 Physics Department, Royal Institute of Technology, Stockholm, Sweden
150 Departments of Physics & Astronomy and Chemistry, Stony Brook University, Stony Brook NY, United States of America
151 Department of Physics and Astronomy, University of Sussex, Brighton, United Kingdom
152 School of Physics, University of Sydney, Sydney, Australia
153 Institute of Physics, Academia Sinica, Taipei, Taiwan
154 Department of Physics, Technion: Israel Institute of Technology, Haifa, Israel
155 Raymond and Beverly Sackler School of Physics and Astronomy, Tel Aviv University, Tel Aviv, Israel
156 Department of Physics, Aristotle University of Thessaloniki, Thessaloniki, Greece
157 International Center for Elementary Particle Physics and Department of Physics, The University of Tokyo, Tokyo, Japan
158 Graduate School of Science and Technology, Tokyo Metropolitan University, Tokyo, Japan
159 Department of Physics, Tokyo Institute of Technology, Tokyo, Japan
160 Tomsk State University, Tomsk, Russia
Department of Physics, University of Toronto, Toronto ON, Canada
(a) INFN-TIFPA; (b) University of Trento, Trento, Italy
(b) TRIUMF, Vancouver BC; (b) Department of Physics and Astronomy, York University, Toronto ON, Canada
Faculty of Pure and Applied Sciences, and Center for Integrated Research in Fundamental Science and Engineering, University of Tsukuba, Tsukuba, Japan
Department of Physics and Astronomy, Tufts University, Medford MA, United States of America
Department of Physics and Astronomy, University of California Irvine, Irvine CA, United States of America
(a) INFN Gruppo Collegato di Udine, Sezione di Trieste, Udine; (b) ICTP, Trieste; (c) Dipartimento di Chimica, Fisica e Ambiente, Università di Udine, Udine, Italy
Department of Physics and Astronomy, University of Uppsala, Uppsala, Sweden
Department of Physics, University of Illinois, Urbana IL, United States of America
Instituto de Física Corpuscular (IFIC), Centro Mixto Universidad de Valencia - CSIC, Spain
Department of Physics, University of British Columbia, Vancouver BC, Canada
Department of Physics and Astronomy, University of Victoria, Victoria BC, Canada
Department of Physics, University of Warwick, Coventry, United Kingdom
Waseda University, Tokyo, Japan
Department of Particle Physics, The Weizmann Institute of Science, Rehovot, Israel
Department of Physics, University of Wisconsin, Madison WI, United States of America
Fakultät für Physik und Astronomie, Julius-Maximilians-Universität, Würzburg, Germany
Fakultät für Mathematik und Naturwissenschaften, Fachgruppe Physik, Bergische Universität Wuppertal, Wuppertal, Germany
Department of Physics, Yale University, New Haven CT, United States of America
Yerevan Physics Institute, Yerevan, Armenia
Centre de Calcul de l’Institut National de Physique Nucléaire et de Physique des Particules (IN2P3), Villeurbanne, France
Academia Sinica Grid Computing, Institute of Physics, Academia Sinica, Taipei, Taiwan
(a) Also at Department of Physics, King’s College London, London, United Kingdom
(b) Also at Institute of Physics, Azerbaijan Academy of Sciences, Baku, Azerbaijan
(c) Also at Novosibirsk State University, Novosibirsk, Russia
d) Also at TRIUMF, Vancouver BC, Canada
(e) Also at Department of Physics & Astronomy, University of Louisville, Louisville, KY, United States of America
(f) Also at Physics Department, An-Najah National University, Nablus, Palestine
(g) Also at Department of Physics, California State University, Fresno CA, United States of America
(h) Also at Department of Physics, University of Fribourg, Fribourg, Switzerland
(i) Also at Il Physikalisches Institut, Georg-August-Universität, Göttingen, Germany
(j) Also at Departamento de Física de la Universitat Autonoma de Barcelona, Barcelona, Spain
(k) Also at Departamento de Física e Astronomia, Faculdade de Ciencias, Universidade do Porto, Portugal
(l) Also at Tomsk State University, Tomsk, and Moscow Institute of Physics and Technology State University, Dolgoprudny, Russia
(m) Also at The Collaborative Innovation Center of Quantum Matter (CICQM), Beijing, China
(n) Also at Universita di Napoli Parthenope, Napoli, Italy
(o) Also at Institute of Particle Physics (IPP), Canada
(p) Also at Horia Hulubei National Institute of Physics and Nuclear Engineering, Bucharest, Romania
(q) Also at Department of Physics, St. Petersburg State Polytechnical University, St. Petersburg, Russia
(r) Also at Borough of Manhattan Community College, City University of New York, New York City, United States of America
* Also at Department of Financial and Management Engineering, University of the Aegean, Chios, Greece
\textsuperscript{b} Also at Centre for High Performance Computing, CSIR Campus,Rosebank, Cape Town, South Africa
\textsuperscript{c} Also at Louisiana Tech University, Ruston LA, United States of America
\textsuperscript{d} Also at Institutio Catalana de Recerca i Estudis Avancats, ICREA, Barcelona, Spain
\textsuperscript{e} Also at Graduate School of Science, Osaka University, Osaka, Japan
\textsuperscript{f} Also at Fakultät für Mathematik und Physik, Albert-Ludwigs-Universität, Freiburg, Germany
\textsuperscript{g} Also at Institute for Mathematics, Astrophysics and Particle Physics, Radboud University Nijmegen/Nikhef, Nijmegen, Netherlands
\textsuperscript{h} Also at Department of Physics, The University of Texas at Austin, Austin TX, United States of America
\textsuperscript{i} Also at Institute of Theoretical Physics, Ilia State University, Tbilisi, Georgia
\textsuperscript{j} Also at CERN, Geneva, Switzerland
\textsuperscript{k} Also at Georgian Technical University (GTU), Tbilisi, Georgia
\textsuperscript{l} Also at Ochadai Academic Production, Ochanomizu University, Tokyo, Japan
\textsuperscript{m} Also at Manhattan College, New York NY, United States of America
\textsuperscript{n} Also at Departamento de Física, Pontificia Universidad Católica de Chile, Santiago, Chile
\textsuperscript{o} Also at Department of Physics, The University of Michigan, Ann Arbor MI, United States of America
\textsuperscript{p} Also at The City College of New York, New York NY, United States of America
\textsuperscript{q} Also at Departamento de Física Teórica y del Cosmos, Universidad de Granada, Granada, Portugal
\textsuperscript{r} Also at Department of Physics, California State University, Sacramento CA, United States of America
\textsuperscript{s} Also at Moscow Institute of Physics and Technology State University, Dolgoprudny, Russia
\textsuperscript{t} Also at Departement de Physique Nucleaire et Corpusculaire, Université de Genève, Geneva, Switzerland
\textsuperscript{u} Also at Institut de Física d’Altes Energies (IFAE), The Barcelona Institute of Science and Technology, Barcelona, Spain
\textsuperscript{v} Also at School of Physics, Sun Yat-sen University, Guangzhou, China
\textsuperscript{w} Also at Institute for Nuclear Research and Nuclear Energy (INRNE) of the Bulgarian Academy of Sciences, Sofia, Bulgaria
\textsuperscript{x} Also at Faculty of Physics, M.V.Lomonosov Moscow State University, Moscow, Russia
\textsuperscript{y} Also at National Research Nuclear University MEPhI, Moscow, Russia
\textsuperscript{z} Also at Department of Physics, Stanford University, Stanford CA, United States of America
\textsuperscript{a} Also at Institute for Particle and Nuclear Physics, Wigner Research Centre for Physics, Budapest, Hungary
\textsuperscript{b} Also at Giresun University, Faculty of Engineering, Turkey
\textsuperscript{c} Also at CPPM, Aix-Marseille Université and CNRS/IN2P3, Marseille, France
\textsuperscript{d} Also at Department of Physics, Nanjing University, Jiangsu, China
\textsuperscript{e} Also at Institute of Physics, Academia Sinica, Taipei, Taiwan
\textsuperscript{f} Also at University of Malaya, Department of Physics, Kuala Lumpur, Malaysia
\textsuperscript{g} Also at LAL, Univ. Paris-Sud, CNRS/IN2P3, Université Paris-Saclay, Orsay, France
