Received 24 July 1996; revised 17 September 1996

3-Methylfuran-2(5H)-one (1a), a precursor of strigol and its analogues, is prepared in a highly efficient manner by a regiocontrolled alcoholysis of citraconic anhydride and subsequent reduction via the mixed anhydride 5c.

The 3-methylfuran-2(5H)-one moiety 1a is a common structural feature of all known "strigolactones", such as (+)-strigol, which are naturally occurring germination stimulants of seeds of the parasitic weeds Striga and Orobanche sp.1-4 Moreover, structure-activity relationship studies revealed that the presence of this structural unit is essential to retain full biological activity, results of which will be published separately.5

Alcoholysis of 2 in the presence of dicyclohexylamine (DCA) with either methanol or 4-methoxybenzyl alcohol gave the esters 3a and 3b, respectively, isolated as the DCA salts, in high yield (80%) and with high regioselectivity (>90%). In our first approach the DCA salts 3a,b were converted into the corresponding carboxylic acids 4a,b by acidification with citric acid or potassium hydrogen sulfate,* followed by treatment with ethyl chloroformate in the presence of triethylamine to give the mixed anhydrides 5a,b. Removal of the Et3N ■ HCl precipitate by filtration, immediately followed by addition of the filtrate containing 5a,b to a saturated aqueous solution of sodium borohydride, smoothly produced 1a.17 After conventional workup, butenolide 1a was isolated in a high overall yield (~80% from crude 3a,b) after purification by fractional distillation under reduced pressure. The choice of the 4-methoxybenzyl ester was advantageous because carboxylic acid 4b is much more stable than 4a. However, the formation of 4-methoxybenzyl alcohol during the reduction process severely complicated the purification of 1a by distillation. A considerable improvement of the above procedure is the direct formation of mixed anhydride 5c from 3a (Scheme). This could be accomplished by treatment of 3a with isobutyl chloroformate, which circumvented the need to isolate carboxylic acid 4a. In this experimental setup ethyl chloroformate is not a suitable reagent, as a considerable amount of the corresponding ethyl ester of 4a was formed under these conditions. The mixed anhydride 5c was then immediately subjected to reduction with NaBH4, using a reversed addition procedure, i.e. addition of a saturated aqueous solution of NaBH4 to 5c, which avoids a laborious extractive workup. Crude butenolide

In view of our interest in the synthesis of simple, biologically active analogues of strigol, which are suitable for weed control purposes,6,7 a convenient multigram preparation of 1a is required, using cheap chemicals. This compound can readily be transformed into the corresponding 5-bromo derivative 1b, which is the D-ring precursor in the synthesis of the strigolactones and their analogues.8 Several procedures for the synthesis of 1a have been reported, but none of them fulfills these criteria satisfactorily.7,9-15 The present paper deals with an improved procedure for the preparation of 3-methylfuran-2(5H)-one (1a).

An attractive cheap, commercially available starting material is citraconic anhydride (2), as it only requires a condensation of citraconic anhydride and subsequent reduction via the desired regiocontrolled fashion in an indirect manner, as is outlined in the Scheme.
3-Methylfuran-2(5H)-one (1a) 

To a cooled (—10°C) solution of DCA salt 3a (65 g, 0.20 mol) in CHCl₃ (150 mL) isobutyl chloroformate (30 g, 0.22 mol) was gradually added with stirring. During the addition a precipitate of dicyclohexylamine chlorohydrate gradually settled. The mixture was stored overnight at ca. —10°C. Then THF (150 mL) was added and the mixture was allowed to stand for 1 h at the same temperature. The precipitate was removed by filtration, while cooling the filtrate (0°C), and washed with THF (150 mL). To the filtrate containing mixed anhydride 5c, a cold solution of NaBH₄ (15 g, 0.4 mol) in water (30 mL) was added at 0°C, while stirring vigorously, over a 1 h period. Stirring was continued for 2 h at the same temperature and the precipitate was removed by filtration and washed with Et₂O. The filtrate was carefully concentrated in vacuo and the residue was dissolved in i-Pr₂O and dried (MgSO₄). The solvent was removed in vacuo to give 1a as a colorless oil, which was purified by fractional distillation at low pressure and subsequently passed over a short column of silica gel, using CC₄ as the eluent; yield: 17 g (80%) as a colorless oil; bp 80°C/15 Torr. The 1H NMR data were in full agreement with those reported.¹⁸

(15) Alternative convenient procedures involve the use of \(\alpha\)-methyl-\(\gamma\)-butyrolactone (ref 13) or \(\alpha\)-methylene-\(\gamma\)-butyrolactone (ref 12), which are very expensive starting materials and difficult to prepare.
