Received 1 July 2004/Returned for modification 23 August 2004/Accepted 6 October 2004

Tenofovir disoproxil fumarate (tenofovir DF) was studied in combination with rifampin in 24 healthy subjects in a multiple-dose, open-label, single-group, two-period study. All subjects were given tenofovir DF at 300 mg once a day (QD) from days 1 to 10 (period 1). From days 11 to 20 the subjects received tenofovir DF at 300 mg combined with rifampin at 600 mg QD (period 2). The multiple-dose pharmacokinetics of tenofovir (day 10 and 20) and rifampin (day 20) were assessed. The drug-related adverse events (AEs) experienced during this study were mostly mild. Only one grade 3 AE possibly or probably related to the treatment (raised liver enzyme levels) occurred during period 2; the subject was withdrawn from the study. Pharmacokinetic data for 23 subjects were thus evaluable. Point estimates for the mean ratios of tenofovir with rifampin versus tenofovir alone for the area under the concentration-time curve from time zero to 24 h (AU{sub}C{sub}0-24), the maximum concentration of drug in plasma (C{sub}max), and the minimum concentration of drug in plasma (C{sub}min) were 0.88, 0.84, and 0.85, respectively. The 90% classical confidence intervals for AU{sub}C{sub}0-24, C{sub}max, and C{sub}min were 0.84 to 0.92, 0.78 to 0.90, and 0.80 to 0.91, respectively, thus suggesting pharmacokinetic equivalence. Similarly, coadministration of rifampin and tenofovir DF did not result in changes in the values of the tenofovir pharmacokinetic parameters. For rifampin, the values of the pharmacokinetic parameters found in this study were comparable to those found in the literature, indicating that tenofovir DF has no effect on the pharmacokinetics of rifampin. In conclusion, adaptation of either the rifampin or the tenofovir DF dose for the simultaneous treatment of tuberculosis and human immunodeficiency virus (HIV) infection in HIV-infected patients is probably not required.

Coinfection with Mycobacterium tuberculosis and human immunodeficiency virus (HIV) is frequent, particularly in Africa and Asia (3, 14, 18). Simultaneous treatment of tuberculosis and HIV infection may lead to complex combination therapy. Rifampin is a drug of choice for the treatment of tuberculosis. Rifaxin is known to have major pharmacokinetic interactions with HIV protease inhibitors and nonnucleoside reverse transcriptase inhibitors that has been recently approved for use for the treatment of HIV infections in adults. However, no data are available regarding its pharmacokinetics in combination with tuberculosstatic drugs, in particular, rifampin. No influence of rifampin on the pharmacokinetics of tenofovir is expected, because both drugs are metabolized and eliminated in different ways. Tenofovir is eliminated unchanged by glomerular filtration and active tubular secretion (1, 6), while rifampin is extensively metabolized by intestinal and hepatic metabolism (4). However, a pharmacokinetic interaction cannot be excluded.

The clinical trial described here was designed to explore the pharmacokinetics of tenofovir DF with and without rifampin in an effort to establish whether there is a need to adjust the dosage of either medication when the two medications are used for the treatment of patients coinfected with M. tuberculosis and HIV.

**MATERIALS AND METHODS**

**Study design.** The present study was designed to evaluate the effect of 600 mg of rifampin on the pharmacokinetics of 300 mg of tenofovir DF and also to assess whether tenofovir DF has a substantial impact on steady-state exposure to rifampin. This study was a multiple-dose, open-label, single-group, two-period study with 24 healthy volunteers. First, the subjects received tenofovir DF at 300 mg once daily (QD) for 10 days (period 1). At study day 10, a steady-state 24-h pharmacokinetic curve was obtained for tenofovir. During the second period of the study (period 2), tenofovir DF at 300 mg was combined with rifampin at 600 mg QD, again for 10 days. At study day 20, 24-h steady-state pharmacokinetic curves were obtained for tenofovir and rifampin. During the study both tenofovir DF and rifampin had to be taken with breakfast. On the days prior to study days 9 and 19, the subjects reported to the study center for direct observation of dosing with the medications with a standardized breakfast. Subsequently, on the evening of study days 9 and 19 the subjects remained at the study center for two overnight stays and remained at the study center until the mornings of study days 11 and 21, respectively. On days 9, 10, 11, 19, and 20 the subjects received a standardized breakfast of 550 kcal (two slices of white bread, 15 g of low-fat margarine, 14 g of jelly, 150 ml of orange juice, and 150 ml of skim milk). The medication was administered immediately after breakfast with 200 ml of tap water. All other meals and snacks on the pharmacokinetic study days were also standardized. When the subjects took the medication at home, study drugs were administered with breakfast (at least two and at most three slices of wheat bread).

No crossover design was used in this study because rifampin could lead to considerable carryover effects, due to its long-lasting cytochrome P450-inducing effect. To eliminate this effect a longer washout period would be necessary, but this would have significantly prolonged the duration of the study and would have
led to difficulties with subject recruitment and retention. This study was reviewed and approved by the independent ethics committee Arnhem-Nijmegen. Written informed consent was obtained from each study subject prior to the conduct of any study-related activity.

**Study subjects.** Twenty-four healthy male and female subjects were eligible for inclusion in the study. The subjects could be between 18 and 65 years of age with a body weight of at least 50 kg and in good age-appropriate health condition, as established by the individual’s medical history; a physical examination; electrocardiography; and the results of biochemistry, hematology, and urine analyses within the 3 weeks prior to administration of the first dose. Other inclusion criteria were an ability to sign informed consent voluntarily and a willingness to refrain from the use of contact lenses during the treatment with rifampin. Exclusion criteria were as follows: positive tests for HIV, hepatitis B virus, or hepatitis C virus; a tuberculosis skin test reaction of 15 mm or greater; a physical examination showing tuberculosis; pregnancy; breast-feeding; the lack of adequate contraception (e.g., hormonal therapy); a total bilirubin level greater than 1 mg/liter; or a serum creatinine level greater than 1.3 mg/liter.

**Pharmacokinetics.** The concentrations of tenofovir, including the arithmetical means, geometric mean ratios, and 90% confidence interval estimates for the pharmacokinetic parameters for tenofovir, including the arithmetical means, geometric mean ratios, and 90% confidence interval estimates for the pharmacokinetic parameters for tenofovir and rifampin. Table 1 provides a summary of the values of the pharmacokinetic parameters for tenofovir and rifampin. The concentrations of tenofovir and rifampin were calculated by noncompartmental methods by use of the WinNonlin software package (version 4.1; Pharsight Corporation, Mountain View, Calif.) and the log–linear trapezoidal rule. On the basis of the individual plasma concentration–time data, the following pharmacokinetic parameters were determined: the area under the plasma concentration–time curve (AUC) from time zero to 24 h (AUC\(_{0–24}\), in milligram–hour per liter), the maximum concentration of drug in plasma (C\(_{\text{max}}\), in milligrams per liter), the time to reach C\(_{\text{max}}\) (T\(_{\text{max}}\), in hours), the minimum concentration drug in plasma (C\(_{\text{min}}\), in milligrams per liter), the apparent elimination half-life (t\(_{1/2}\)), and the apparent oral clearance (CL/F) in liters per hour. AUC\(_{0–24}\), where C\(_{\text{max}}\) is the last quantifiable concentration, was calculated for rifampin. C\(_{\text{min}}\) and CL/F were not calculated for rifampin.

**RESULTS**

### Demographics.

Twenty-four subjects (13 males, 11 females) were enrolled in this trial. One male subject was black; all other subjects were Caucasian. The mean age of the subjects was 41 years (range, 20 to 63 years). The mean body weight was 77 kg (range, 58 to 97 kg), and the mean height was 1.75 m (range, 1.59 to 1.88 m).

**Pharmacokinetic analysis.** The pharmacokinetic parameters for tenofovir and rifampin were calculated by use of the WinNonlin software package (version 4.1; Pharsight Corporation, Mountain View, Calif.) and the log–linear trapezoidal rule. On the basis of the individual plasma concentration–time data, the following pharmacokinetic parameters were determined: the area under the plasma concentration–time curve (AUC) from time zero to 24 h (AUC\(_{0–24}\), in milligram–hour per liter), the maximum concentration of drug in plasma (C\(_{\text{max}}\), in milligrams per liter), the time to reach C\(_{\text{max}}\) (T\(_{\text{max}}\), in hours), the minimum concentration drug in plasma (C\(_{\text{min}}\), in milligrams per liter), the apparent elimination half-life (t\(_{1/2}\)), and the apparent oral clearance (CL/F) in liters per hour. AUC\(_{0–24}\), where C\(_{\text{max}}\) is the last quantifiable concentration, was calculated for rifampin. C\(_{\text{min}}\) and CL/F were not calculated for rifampin.

### Statistical analysis.

Statistical analyses were performed with SPSS software (version 11.0; SPSS Inc., 1989 to 1999). Descriptive statistics were calculated with Excel 2000 software (Microsoft Corporation, 1985 to 1999). Evaluation of the AUC\(_{0–24}\) and the C\(_{\text{max}}\) of tenofovir was the main objective of this trial. These parameters are considered the primary characteristics for the extent and the rate of drug absorption, respectively. The bioequivalence of tenofovir was determined by comparing the values of the relevant pharmacokinetic parameters obtained with the test treatment (tenofovir DF and rifampin on study day 20) to those obtained with the reference treatment (tenofovir DF alone on study day 10) by using the following statistical methods. The AUC\(_{0–24}\), C\(_{\text{max}}\) and C\(_{\text{min}}\) of tenofovir were reported for study day 10 and study day 20 together by use of the ratios of the values on study day 20/values on study day 10. The arithmetic means and standard deviations are given for study day 20 and study day 10. The geometric mean ratios and 90% confidence intervals for AUC\(_{0–24}\), C\(_{\text{max}}\), and C\(_{\text{min}}\) were calculated. Treatments were considered bioequivalent if the respective 90% confidence intervals for AUC\(_{0–24}\), C\(_{\text{max}}\), and C\(_{\text{min}}\) were included within the bioequivalence range of 80 to 125% (20). The values of the pharmacokinetic parameters for rifampin were compared with data from the literature by the use of descriptive statistics. The study was powered for the tenofovir C\(_{\text{max}}\) by using nQuery software, and a sample size of 15 was required to achieve an 80% power to reject the null hypothesis that the two treatments are not equivalent in favor of the alternative hypothesis that the means of the two treatments are equivalent when the expected difference is 0.000. By this approach, a sample size of 15 would provide a 93% power for AUC\(_{0–24}\). By considering the possibility that the subjects would drop out and/or that some difficulties with sample or pharmacokinetic analysis with some subjects would occur, 24 subjects were enrolled in this study.
The study was designed to investigate whether rifampin influences the pharmacokinetics of tenofovir. The study showed that bioequivalence could be suggested for tenofovir DF combined with rifampin and tenofovir DF given alone and that the combination of tenofovir DF with rifampin was generally well tolerated, as only one patient prematurely discontinued from study.

The confidence intervals for AUC and \( C_{\text{min}} \) were 0.84 to 0.92 and 0.80 to 0.91, respectively, while the confidence interval was 0.85 (0.80 to 0.91) for AUC_{0-24}, \( C_{\text{max}} \), and \( C_{\text{min}} \), respectively, suggesting pharmacokinetic equivalence when tenofovir DF was dosed with or without rifampin.

Figure 1 illustrates the effects of rifampin on the mean concentration-time profiles of tenofovir. Table 2 presents the values of the pharmacokinetic parameters for rifampin when it was combined with tenofovir and the values of the pharmacokinetic parameters of rifampin from the literature (4, 15). The values of the pharmacokinetic parameters for rifampin when it was combined with tenofovir are comparable to those in the literature when rifampin is administered with food, suggesting pharmacokinetic equivalence when tenofovir DF with rifampin was dosed.

**DISCUSSION**

This study was designed to investigate whether rifampin influences the pharmacokinetics of tenofovir. The study showed that bioequivalence could be suggested for tenofovir DF combined with rifampin and tenofovir DF given alone and that the combination of tenofovir DF with rifampin was generally well tolerated, as only one patient prematurely discontinued from study.

The confidence intervals for AUC and \( C_{\text{min}} \) were 0.84 to 0.92 and 0.80 to 0.91, respectively, while the confidence interval was 0.85 (0.80 to 0.91) for AUC_{0-24}, \( C_{\text{max}} \), and \( C_{\text{min}} \), respectively, suggesting pharmacokinetic equivalence when tenofovir DF was dosed with or without rifampin.

0.85 (0.80 to 0.91) for AUC_{0-24}, \( C_{\text{max}} \), and \( C_{\text{min}} \), respectively, suggesting pharmacokinetic equivalence when tenofovir DF was dosed with or without rifampin.

Figure 1 illustrates the effects of rifampin on the mean concentration-time profiles of tenofovir. Table 2 presents the values of the pharmacokinetic parameters for rifampin when it was combined with tenofovir and the values of the pharmacokinetic parameters of rifampin from the literature (4, 15). The values of the pharmacokinetic parameters for rifampin when it was combined with tenofovir are comparable to those in the literature when rifampin is administered with food, suggesting that tenofovir has no influence on rifampin exposure.

**Safety.** All 24 subjects reported one or more AEs at some time during the study. No subject experienced a grade 4 AE or a serious AE in total, 160 grade 1 or grade 2 AEs were reported. A total of 102 AEs were judged to be possibly or probably related to a study drug(s). During treatment with tenofovir DF (period 1), 33 possibly or probably related AEs were reported, while during period 2 (tenofovir DF combined with rifampin), 69 possibly or probably related AEs were reported. Of the 69 AEs reported during period 2, 24 AEs were related only to rifampin. Each subject reported discoloration of the urine. Most of the study drug-related AEs were mild (85% were grade 1 in severity). All AEs resolved after the withdrawal of treatment.

All 24 subjects completed treatment period 1 (tenofovir DF alone). The most common AEs that were reported during treatment with tenofovir DF were fatigue, headache, and gastrointestinal disorders.

During period 2 one subject was withdrawn from the study due to several complaints, which were rash, headaches, abdominal disorders, fatigue, somnolence, and dizziness. The study medications were stopped on study day 15. At the follow-up visit, 5 days later, the subject developed elevated liver enzyme levels, which were judged to be a grade 3 AE. Nine days after the first follow-up visit the liver enzyme levels returned to normal. The AEs that occurred during the combination treatment with tenofovir DF and rifampin consisted mainly of flu-like symptoms (e.g., fatigue, headache, and gastrointestinal disorders) and urine discoloration, which are well-known AEs of rifampin (7).

No clinically significant hematology or urinalysis values were observed in this study.

* Values are means (standard deviations).
0.78 to 0.90 for $C_{\text{max}}$. By definition, bioequivalence was proven for AUC and $C_{\text{min}}$ but was only suggested for $C_{\text{max}}$.

The tenofovir DF dose used in this study (300 mg QD) is the dose recommended for the treatment of HIV infection in adults (11). The rifampin dose used (600 mg QD) is an accepted regimen for the treatment of tuberculosis in patients weighing more than 50 kg (7). A previous study (2) has shown that steady-state conditions for rifampin are generally achieved after the sixth daily dose of rifampin at 600 mg. To ensure the achievement of steady-state pharmacokinetics, subjects were given tenofovir DF combined with rifampin for 10 days before pharmacokinetic assessment.

The reason for the lower observed tenofovir levels is unknown. Several mechanisms could contribute to this interaction. Because tenofovir is not metabolized and is eliminated unchanged by a combination of glomerular filtration and active tubular secretion (1, 6), it is unlikely that the inducing effect of rifampin on hepatic and intestinal cytochrome P450 enzymes (especially CYP3A4) (8) is the mechanism responsible for this effect. This is supported by no apparent changes in the tenofovir $t_{1/2}$ and no clinically relevant effects of rifampin on the tenofovir $C_{\text{min}}$.

Similarly, as tenofovir minimally binds to proteins in human plasma or serum (≤0.7 and 7.2%, respectively) (11), altered for AUC and $C_{\text{max}}$ interactions. AEs of both tenofovir and rifampin and occurred in a total of 49 subjects, 34 (69%) of whom had hypersensitivity reactions. Gastrointestinal disorders are well-known effect of rifampin. Gastrointestinal disorders are well-known due to one or both of the diseases. Second, 23 of the 24 subjects of this study were infected patients coinfected with the diseases. Therefore, the reasons for the tenofovir levels observed in the subjects with the diseases. Second, 23 of the 24 subjects of this study were infected patients coinfected with the diseases. Second, 23 of the 24 subjects of this study were infected patients coinfected with the diseases.

In conclusion, the data from this study demonstrate that the addition of rifampin to tenofovir DF is well tolerated, and the small decrease in plasma tenofovir levels during combination treatment suggests that these drugs can be coadministered without the need for dose adjustments. This implies that standard doses should be a starting point for the use of these medications by HIV-infected patients. Additional pharmacokinetic studies in a clinical setting are warranted to confirm the findings of this study.
