CONSTRUCTIVE POINTFREE TOPOLOGY ELIMINATES
NON-CONSTRUCTIVE REPRESENTATION THEOREMS FROM
RIESZ SPACE THEORY

BAS SPITTERS

Abstract. In Riesz space theory it is good practice to avoid representation
theorems which depend on the axiom of choice. Here we present a general
methodology to do this using pointfree topology. To illustrate the technique we
show that almost f-algebras are commutative. The proof is obtained relatively
straightforward from the proof by Buskes and van Rooij by using the pointfree
Stone-Yosida representation theorem by Coquand and Spitters.

The Stone-Yosida representation theorem for Riesz spaces [LZ71, Zaa83] shows
how to embed every Riesz space into the Riesz space of continuous functions on its
spectrum.

Theorem 1. [Stone-Yosida] Let $R$ be an Archimedean Riesz space (vector lattice)
with unit. Let $\Sigma$ be its (compact Hausdorff) space of representations. Define the
continuous function $\hat{r}(\sigma) := \sigma(r)$ on $\Sigma$. Then $r \mapsto \hat{r}$ is a Riesz embedding of $R$ into
$C(\Sigma, R)$.

The theorem is very convenient, but sometimes better avoided, since it leads out
of the theory of Riesz spaces. To quote Zaanen [Zaa97]:

Direct proofs, although sometimes a little longer than proofs by
means of representation [theorems], often reveal more about the
situation under discussion.

Similar concerns where discussed by Buskes, de Pagter and van Rooij [BvR89,
BdPvR91]. They proposed to avoid the use of the axiom of choice by restricting the
size of the Riesz spaces [BvR89]. We provide a solution based on pointfree topology,
which like [BvR89] avoids also the countable axiom of choice, but moreover avoids
the axiom of excluded middle \footnote{P \lor \neg P}. This allows the results to be applied in non-standard
contexts. For instance, one can translate a theorem about one C*-algebra to a the-
orem about a continuous field of C*-algebras [BM97, BM00a, BM00b, BM06]. In
turn, the results about commutative C*-algebras may be obtained directly using
Riesz spaces [CS08]. This is used in applications of topos theory to quantum the-
ory [HLS07].

Our strategy is as follows. First we replace the topological space of representa-
tions by a locale, a point-free space. This typically removes the need of the axiom
of choice [Mul03]. Then we proceed to use pointfree topology, locale theory using
a only basis for the topology [Sam87]. Since the space of representations of a Riesz
space is compact Hausdorff, it can be described explicitly by the finite covering
relation on the lattice of basic opens. This lattice can be defined directly using the
Riesz space structure [Coq05, CS05].
To illustrate the method we will reprove the results by Buskes and van Rooij [BvR00].

1. Preliminaries

**Definition 1.** A Riesz space is a vector space with compatible lattice operations — i.e. \( f \land g + f \lor g = f + g \) and if \( f \geq 0 \) and \( a \geq 0 \), then \( af \geq 0 \). A (strong) unit \( 1 \) in a Riesz space is an element such that for all \( f \) there exists a natural number \( n \) such that \( |f| \leq n \cdot 1 \). A Riesz space is Archimedean if for all \( n \), \( n|x| \leq y \) implies that \( x = 0 \).

1.1. Topologies, locales, lattices. A topological space may be presented in its familiar set theoretic form, as such it is a complete distributive lattice of open sets with the operations of union and intersection. The category of frames has as objects lattices with a finitary meets and infinitary joins such that \( \land \) distributes over \( \lor \). Frame maps preserve this structure. A continuous function \( f : X \to Y \) defines a frame map \( f^{-1} : O(Y) \to O(X) \). Since this map goes in the reverse direction it is often convenient to consider the category of locales, the opposite of the category of frames. In fact, there is a categorical adjunction between the category of locales and the category of topological spaces. This restricts to an equivalence of categories for compact Hausdorff spaces and compact regular locales. In general, the axiom of choice is needed to move from locales to topological spaces. Hence, by staying on the localic side it is often possible to avoid the axiom of choice. However, one can go even further. Since compact locales are determined by the finitary coverings one may restrict one’s attention to the finitary covering relation on a base of the topology. This base is a normal\(^2\) distributive lattice.

For the spectrum of a Riesz space \( R \) a base for the topology can be described very explicitly. Recall that a base for the topology of the spectrum \( \Sigma \) is defined by the opens \( \{ \sigma | \hat{a}(\sigma) > 0 \} \). Let \( P \) denote the set of positive elements of \( R \). For \( a, b \) in \( P \) we define \( a \leq b \) to mean that there exists \( n \) such that \( a \leq nb \). The following proposition is proved in [CS05] and involves only elementary considerations on Riesz spaces.

**Proposition 1.** \( L(R) := (P, \lor, \land, 1, 0, \leq) \) is a distributor lattice. In fact, if we define \( D : R \to L(R) \) by \( D(a) := a^+ \), then \( L(R) \) is the free lattice generated by \( \{ D(a) | a \in R \} \) subject to the following relations:
1. \( D(a) = 0 \), if \( a \leq 0 \);
2. \( D(1) = 1 \);
3. \( D(a) \land D(-a) = 0 \);
4. \( D(a + b) \leq D(a) \lor D(b) \);
5. \( D(a \lor b) = D(a) \lor D(b) \).

We have \( D(a) \leq D(b) \) if and only if \( a^+ \leq b^+ \) and \( D(a) = 0 \) if and only if \( a \leq 0 \). We write \( a \in (p, q) := (a - p) \land (q - a) \) and observe that this is an element of \( R \).

For \( a \) in \( R \) we define its norm \( \|a\| = \inf\{q | a \leq q \} \).

The corresponding localic\(^3\) (complete distributive lattice) \( \Sigma \) is the one defined by the same generators and relations together with the relation \( D(a) = \bigvee_{s > 0} D(a - s) \). The generators and relations above may also be read as a propositional geometric

\[^2\]A lattice is normal if for all \( b_1, b_2 \) such that \( b_1 \lor b_2 = \top \) there are \( c_1, c_2 \) such that \( c_1 \land c_2 = \bot \) and \( c_1 \lor b_1 = \top \) and \( c_2 \lor b_2 = \top \). The opens of a normal topological space form a normal lattice.

\[^3\]From this point onwards \( \Sigma \) is the spectrum considered as a locale. If we want to treat it as a topological space we write \( pt \Sigma \).
theory [Vic07] by reading $\leq$ as $\Rightarrow$. A model $m$ of this theory defines a representation $\sigma_m$ of the Riesz space by

$$\sigma_m(a) := \{q|m \models D(q \cdot 1 - a)\}, \{q|m \models D(a - q \cdot 1)\},$$

where the right hand side is a Dedekind cut in the rationals and hence a real number. Such a $\sigma_m$ is a point of the locale $\Sigma$. This motivates the interpretation of $D(a)$ as $\{\sigma|\hat{a}(\sigma) > 0\}$: the models which make the proposition $D(a)$ true coincide with the points $\sigma$ such that $\hat{a}(\sigma) > 0$. Proving that there are enough such models/points requires the axiom of choice. We avoid this axiom by working with the propositions/opens instead.

**Theorem 2.** [Localic Stone-Yosida] The map $\hat{\cdot} : R \rightarrow \text{Loc}(\Sigma, \mathbb{R})$ defined by the frame map $\hat{a}(p, q) := a \in (p, q)$ is a norm-preserving Riesz morphism. Its image is dense with respect to the uniform topology on $\text{Loc}(\Sigma, \mathbb{R})$.

**Proof.** The map $\hat{\cdot} : R \rightarrow \text{Loc}(\Sigma, \mathbb{R})$ is norm-preserving; see [CS05]. It remains to prove the density. For this consider a natural number $N$ and a continuous $f$ on $\Sigma$ such that $0 \leq f \leq 1$. We need to find an element $a$ of $R$ such that $\hat{a}$ is close to $f$. The set $\bigcup_{k=0}^{N} f \in ((k-1)/N, (k+1)/N)$ covers $\Sigma$. By Proposition 3.1 of [Coq05] there exists a partition of unity $p_i$ in the Riesz space such that $\sum p_i = 1$ and $D(p_i)$ is contained in some open $f \in ((k_i - 1)/N, (k_i + 1)/N)$ in $\Sigma$. Concretely, $p_i \equiv (f - (k_i - 1)/N) \cap ((k_i + 1)/N - f)$. Consequently,

$$|f - \sum k_i \hat{p}_i| = |f \sum \hat{p}_i - \sum k_i \hat{p}_i| = |\sum (f - k_i) \hat{p}_i| \leq \frac{1}{N}.$$

The map $\hat{\cdot}$ is a Riesz embedding if $R$ is Archimedean.

**Corollary 1.** There is a norm-preserving Riesz morphism of $R$ into an f-algebra such that the image is dense.

The axiom of choice implies that compact regular locales have enough points and hence we obtain the more familiar formulation of the theorem by working with the topological space $\text{pt } \Sigma$ of the points of the spectrum. However, in practice, only the localic version is needed.

**Corollary 2.** [Stone-Yosida] The map $\hat{\cdot} : R \rightarrow C(\text{pt } \Sigma, \mathbb{R})$ defined by the frame map $\hat{a}(p, q) := a \in (p, q)$ is a norm-preserving Riesz morphism. Its image is dense with respect to the uniform topology on $C(\text{pt } \Sigma, \mathbb{R})$.

2. **The results**

**Definition 2.** An almost f-algebra is a Riesz space with multiplication such that $a \cdot b \geq 0$ if $a, b \geq 0$, and $a \wedge b = 0$ implies $a \cdot b = 0$.

If $E$ is a Riesz space, a bilinear map $A$ of $E \times E$ into a vector space $F$ is called *orthosymmetric* if

$$f \wedge g = 0 \Rightarrow A(f, g) = 0$$

for all $f, g \in E$.

A partition of unity is a list $u_i$ such that $\sum u_i = 1$ and $0 \leq u_i \leq 1$. If $u, v$ are partitions of unity in an almost f-algebra, then so is $u \cdot v$: $\sum u_i v_j = 1 \cdot \sum v_j$. 
Theorem 3. Let $E$ be a Riesz space with unit and let $F$ be Archimedean and let $A$ be an orthosymmetric positive bilinear map $E \times E \to F$. Let $\bar{E}$ be an $f$-algebra in which $E$ is dense and let $F'$ be the uniform completion of $F$. Then $A$ extends uniquely to a orthosymmetric positive bilinear map from $\bar{E} \times \bar{E}$ to $F'$ and $A(f, g) = A(1, f g)$ for all $f, g$ in $E$.

Proof. Let $f, g$ be in $E$.

$$A(f, g) = A(f^+, g^+) + A(f^-, g^-) - A(f^-, g^+) + A(f^+, g^-).$$

So, it suffices to consider the case $0 \leq f, g \leq 1$. Let $k$ be a natural number. Define $u_n := k(f \vee \frac{n}{k} \wedge \frac{n+1}{k})$, whenever $0 \leq n < k$. Define $v_0 := 1 - u_0$ and $v_n := u_n - u_{n+1}$ and $v_k := u_k$. The set $\{v_0, \ldots, v_k\}$ is a partition of unity — that is, $\sum v_i = 1$ and $0 \leq v_i \leq 1$. Moreover, $v_n \perp v_m$, whenever $|n - m| > 1$ and such that $|v_n - \frac{1}{2}v_n| \leq \frac{1}{k}$. By repeating a similar construction for $g$ we find a partition of unity $v_i$. Then $w_{ij} := v_i v_j$ is again a partition of unity. For convenience, we reindex $w$ by one natural number to obtain a sequence $w_n$. We define $\alpha_n, \beta_n$ such that $|f - \sum \alpha_n u_n| < \frac{1}{k}$ and $|g - \sum \beta_n u_n| < \frac{1}{k}$.

Let $\varepsilon = \frac{1}{k}$. Set $f' := \sum \alpha_n u_n$, $g' := \sum \beta_n w_n$ and $h' := \sum \alpha_n \beta_n w_n$. Then

$$|A(f, g) - A(f', g')| = |A(f - f', g) + A(f', g - g')| \leq \varepsilon A(1, 1) + \varepsilon A(1, 1)$$

since $|f - f'|, |g - g'| \leq \varepsilon$ and $A$ is positive. Thus, it suffices to show that

$$|A(f', g') - A(1, h')| \leq 2\varepsilon A(1, 1).$$

Observe that for all $n, m$ in $\{1, \ldots, N\},$

- if $|n - m| > 1$, then $w_n \perp w_m$, so $A(w_n, w_m) = 0$;
- if $|n - m| \leq 1$, then $|\alpha_n - \alpha_m| \leq 2\varepsilon$.

It follows that

$$|A(f', g') - A(1, h')| = \bigg|\sum \alpha_n \beta_m A(w_n, w_m) - \sum \alpha_m \beta_n A(w_n, w_m)\bigg|$$

$$\leq \sum |\alpha_n - \alpha_m| |\beta_m| A(w_n, w_m)$$

$$\leq 2\varepsilon \sum A(w_n, w_m) = 2\varepsilon A(1, 1)$$

The last inequality follows from the observation above and the inequality $|\beta_m| \leq 1$.

Changing the roles of the $\alpha$s and $\beta$s we have that $|A(g', f') - A(1, h')| \leq 2\varepsilon A(1, 1)$. Hence $|A(f', g') - A(g', f')| \leq 4\varepsilon A(1, 1)$ and $|A(f, g) - A(g, f)| \leq 8\varepsilon A(1, 1)$. Finally, $|h' - f' g'| \leq |\sum \alpha_m \beta_m w_n w_m - \sum \alpha_m \beta_m w_n w_m| \leq \sum |\alpha_n - \alpha_m| |\beta_m| w_n w_m \leq 2\varepsilon$. Hence $|h' - f g|$ is small. Since $F$ is Archimedean, $A(f, g) = A(1, f g)$. \[\square\]

The completion of $E$ and $F$ in the previous proof are used to define the multiplication on $\bar{E}$ and to be able to extend $A$ to this completion of $E$. This, however, can be avoided as follows. The joint partition of unity can be obtained as in Theorem 2. The proof above then shows that for each $\varepsilon$, $|A(f, g) - A(g, f)| \leq 8\varepsilon A(1, 1)$. This implies the following result.

Corollary 3. Let $E$ and $F$ be Riesz spaces of which $F$ is Archimedean. Let $A$ be an orthosymmetric positive bilinear map $E \times E \to F$. Then

$$A(f, g) = A(g, f) \quad (f, g \in E).$$
Proof. Take $f, g \in E$. Let $E_0$ be the Riesz subspace of $E$ generated by $\{f, g\}$. Then $|f| + |g|$ is a unit in $E_0$. Without restriction, suppose that $E_0$ is $E$. The result is now follows from the previous theorem. \qed

We have proved the following result in an entirely explicit way by a straightforward analysis of the proof by Buskes and van Rooij.

Corollary 4. Every Archimedean almost $f$-algebra is commutative.

3. Internal real numbers

Buskes and van Rooij use the Stone-Yosida representation theorem combined with Dini’s theorem to show that a certain sequence of elements in a Riesz space converges. This can be replaced by applying the following result which does not require the sequence to be decreasing.

Theorem 4. Let $e_n$ be a sequence of expressions in the language of Riesz spaces such that $e_n$ converges constructively when interpreted in the Riesz space of real numbers. Then $e_n$ converges uniformly when interpreted in any Riesz space with strong unit.

Proof. The Riesz space can be (densely) embedded into a space $C(\Sigma)$ and hence its elements may be interpreted as global sections of the real number object in the topos $\text{Sh}(\Sigma)$ of sheaves over $\Sigma$ [Joh02, MLM94]. Now, if $a_n$ converges to 0 in the internal language of $\text{Sh}(\Sigma)$. Then for each $q$ there exists $n$ such that $a_n \leq q$ internally. This is interpreted as: for each $q$ there exists a (finite) cover $U_i$ of $\Sigma$ and $n_i$ such that $a_{n_i} \leq q$ on $U_i$. Taking $n = \min n_i$ we see that $a_n \leq q$ on $\Sigma$. \qed

Sheaf theory may seem to be a very complex tool to use for such a simple lemma, however, when applied in concrete cases we obtain natural results. For instance, Buskes and van Rooij apply Dini’s theorem and the Stone-Yosida representation theorem to prove that the sequence $[(f \land g)h - nf(g \land h)]^+$ converges uniformly. We first prove this for the Riesz space of real numbers. Fix $m$ in $\mathbb{N}$. We may assume that $f, g, h \leq 1$. Moreover, either $f \geq \frac{1}{m}$ or $f \leq \frac{1}{m}$. We may assume that $f \geq \frac{1}{m}$ and similarly that $g, h \geq \frac{1}{m}$. Choosing $n = m^2$ shows that $(f \land g)h \leq 1$ and $nf(g \land h) \geq n \cdot \frac{1}{m} \cdot \frac{1}{m} \geq 1$. Hence if $n \geq m^2$, then $[(f \land g)h - nf(g \land h)]^+ \leq \frac{2}{m}$ in all cases. The interpretation of this statement in the sheaf model $\text{Sh}(\Sigma)$ defined from the spectrum $\Sigma$ of a Riesz space is: there is a finite cover $U_i$ of $\Sigma$ such that $[(f \land g)h - nf(g \land h)]^+ \leq \frac{2}{m}$ is true on each $U_i$. A finite cover gives rise to a partition $u_i$ of unity such that $D(u_i) \subset U_i$. So, that $u_i[(f \land g)h - nf(g \land h)]^+ \leq \frac{2}{m}$ and hence

$$[(f \land g)h - nf(g \land h)]^+ = \sum u_i[(f \land g)h - nf(g \land h)]^+ \leq \frac{2}{m}.$$ 

Takeuti’s use of Boolean valued models [Tak78] to obtain non-standard results from familiar theorems has a similar flavor as Theorem 4. Boolean valued models are a special class of sheaf models.

---

4The case distinction $f \geq \frac{1}{m}$ or $f \leq \frac{1}{m}$ is not constructive/continuous.
4. Conclusion

We have illustrated how the use of locale theory, presented by a normal distributive lattice of basic elements, naturally translates proofs which depend on the axiom of choice to simpler lattice theoretic proofs which avoid the axiom of choice, even in its countable form, and the principle of excluded middle. Buskes and van Rooij had previously proposed different methods to avoid the axiom of choice. An advantage of our approach is that it is valid in any topos. It also provides a logical tool to remove the use of representation theorems from Riesz space theory, the importance of avoiding representation theorems was stressed by Zaanen.

5. Acknowledgments

I would like to thank Gerard Buskes, Thierry Coquand and Arnoud van Rooij for comments on an earlier draft of this paper.
