Search for Lepton Flavour Violation in the $e\mu$ Continuum with the ATLAS Detector in $\sqrt{s} = 7$ TeV $pp$ Collisions at the LHC

The ATLAS Collaboration

Abstract

This paper presents a search for the $t$-channel exchange of an $R$-parity violating scalar top quark ($\tilde{t}$) in the $e^\pm\mu^\mp$ continuum using 2.1 fb$^{-1}$ of data collected by the ATLAS detector in $\sqrt{s} = 7$ TeV $pp$ collisions at the Large Hadron Collider. Data are found to be consistent with the expectation from the Standard Model backgrounds. Limits on $R$-parity-violating couplings at 95% C.L. are calculated as a function of the scalar top mass ($m_{\tilde{t}}$). The upper limits on the production cross section for $pp \rightarrow e\mu X$, through the $t$-channel exchange of a scalar top quark, ranges from 170 fb for $m_{\tilde{t}} = 95$ GeV to 30 fb for $m_{\tilde{t}} = 1000$ GeV.
Search for Lepton Flavour Violation in the $e\mu$ Continuum with the ATLAS Detector in $\sqrt{s} = 7$ TeV $pp$ Collisions at the LHC

Abstract. This paper presents a search for the $t$-channel exchange of an $R$-parity violating scalar top quark ($\tilde{t}$) in the $e^{\pm}\mu^{\mp}$ continuum using 2.1 fb$^{-1}$ of data collected by the ATLAS detector in $\sqrt{s} = 7$ TeV $pp$ collisions at the Large Hadron Collider. Data are found to be consistent with the expectation from the Standard Model backgrounds. Limits on $R$-parity-violating couplings at 95% C.L. are calculated as a function of the scalar top mass ($m_{\tilde{t}}$). The upper limits on the production cross section for $pp \rightarrow e\mu X$, through the $t$-channel exchange of a scalar top quark, ranges from 170 fb for $m_{\tilde{t}} = 95$ GeV to 30 fb for $m_{\tilde{t}} = 1000$ GeV.

1 Introduction

In the Standard Model (SM), direct production of $e^{\pm}\mu^{\mp}$ ($e\mu$) pairs is forbidden in $pp$ collisions due to lepton flavour conservation. However, in many extensions of the SM, lepton flavour violation (LFV) is permitted. In particular, $R$-parity-violating (RPV) supersymmetric (SUSY) models, LFV leptoquarks, and models with additional gauge symmetry allow LFV. Previous searches by the CDF, D0, and ATLAS Collaborations [1–7] have focused on resonant production of a heavy neutral particle which decays into an $e\mu$ pair and have set limits on these models. In addition to resonant $e\mu$ production, RPV SUSY models also allow for LFV interactions through the $t$-channel exchange of a scalar quark. The corresponding Lagrangian term for these RPV processes [8] is $W = -\lambda_{ijk}^{\prime} \bar{u}_i d_k \ell_j$, where $\bar{u}$ denotes the up-type squark field, $d$ is the down-type quark field, $\ell$ represents the lepton field, and $\lambda'$ is the coupling at the production vertex. The indices $i,j,k$ refer to fermion generations. This superpotential couples an up-type squark to a down-type quark and a lepton, allowing for production of $e\mu$ pairs through the $t$-channel exchange of an up-type squark. This paper presents a search for this process in the $e\mu$ continuum using 2.1 fb$^{-1}$ of $pp$ collision data at $\sqrt{s} = 7$ TeV collected by the ATLAS detector at the Large Hadron Collider (LHC).

The cross section for this process is expected to be dominated by the lightest up-type squark, which is taken to be the scalar top quark ($\tilde{t}$) in this analysis. The Feynman diagram for the dominant process, $d\bar{d} \rightarrow e^{-}\mu^{+}$ through the $t$-channel exchange of a $\tilde{t}$, is shown in Fig. 1. The leading-order (LO) partonic differential cross section is calculated as $\frac{d\sigma}{d\ell} = |\lambda_{131}^{\prime}\lambda_{231}^{\prime2}|^2/64\pi s^2 (\ell - m_{\tilde{t}}^2)^2$, where $s$ and $\ell$ are the usual Mandelstam variables in the $dd$ centre-of-mass frame, $N_c = 3$ is the colour factor, $m_{\tilde{t}}$ is the scalar top mass, and $\lambda_{131}^{\prime} (\lambda_{231}^{\prime})$ is the coupling for the vertex $d\ell e^{-} (\mu^{+}\tilde{t})$. The process where the final state leptons have opposite charges to those in Fig. 1 has the same cross section. Diagrams with the $d$ and $\tilde{t}$ independently replaced by $s$ and $\tilde{s}$ quarks are also allowed. The form of the cross section for these diagrams is the same, but the indices on the $\lambda'$ couplings are different. In the case of $ss \rightarrow \mu^{\pm}e^{\mp}$, the cross section depends on $|\lambda_{132}^{\prime}\lambda_{232}^{\prime}|$. For $ds \rightarrow \mu^{\pm}e^{-}$ and $sd \rightarrow \mu^{-}e^{+}$, the cross section depends on $|\lambda_{131}^{\prime}\lambda_{232}^{\prime}|$. Lastly, diagrams with $sd \rightarrow \mu^{\pm}e^{-}$ and $ds \rightarrow \mu^{-}e^{+}$ depend on $|\lambda_{231}^{\prime}\lambda_{132}^{\prime}|$.

Strong limits on RPV couplings have been obtained from low-energy searches [9,10], such as $\mu \rightarrow e\gamma$, $\mu \rightarrow e\nu\nu$, and $Z \rightarrow e\mu$, where superparticles appear in the intermediate state, often in loops. The presence of multiple interfering amplitudes makes the extraction of limits difficult, and it is usually assumed that a single product of couplings dominates. The interference of different diagrams could weaken the limits on a specific product of couplings. Also, these limits depend on...
unknown superparticle masses (including ones other than the scalar top), sometimes in a complex manner.

The HERA experiments searched for an LFV leptoquark in the process $e p \rightarrow \mu X$ [11,12]. These studies also place limits on a potential RPV scalar top. At lower masses (less than about 300 GeV), there would be copious $s$-channel production, and placing limits on specific couplings depends on assumptions about the stop decays. At higher masses, the HERA searches are sensitive to $u$-channel exchange, which can be directly compared to this analysis. The sensitivity of the measurement in this paper is slightly better than at HERA for masses above about 300 GeV. The HERA experiments also searched for scalar top production in both the RPV and gauge boson decay channels [13,14]. Such searches assumed the RPV coupling involved in the scalar top production, $\lambda_{131}^{\prime}$, to be dominant and cannot be directly compared with the results of this paper.

Direct searches at hadron colliders and at HERA for lepton-flavour-conserving scalar leptoquarks [15–24] are also relevant to the search here. The interpretation of such results as limits on a scalar top depends, as for the LFV processes, on the decay branching ratios to the leptons and quarks and hence on assumptions about the other possible decays. Present limits on such leptoquarks at the scalar top masses considered here do not preclude the signal sought in this analysis.

The limits on the couplings associated with the $d\bar{s}$ and $s\bar{d}$ processes are two orders of magnitude lower than those for the $d\bar{d}$ and $s\bar{s}$ couplings [9]. Therefore dominance by same flavour quark scattering processes is assumed in this analysis. As a result, the production cross section for $pp \rightarrow e\mu X$, due to the $t$-channel exchange of a scalar top quark, depends on $\lambda_{131}^{\prime}$, $\lambda_{231}^{\prime}$, $\lambda_{132}^{\prime}$, $\lambda_{232}^{\prime}$, and $m_t$.

2 Detector and Data Sample

The ATLAS detector [25] is a multi-purpose particle detector with a forward-backward symmetric cylindrical geometry and almost $4\pi$ coverage in solid angle [29]. The inner tracking detector (ID) covers $|\eta| < 2.5$ in pseudorapidity $\eta$ and consists of a silicon pixel detector, a silicon microstrip detector, and a transition radiation tracker. The ID is surrounded by a thin superconducting solenoid providing a 2 T magnetic field and by a hermetic calorimeter system, which provides three-dimensional reconstruction of particle showers up to $|\eta| = 4.9$. The muon spectrometer (MS) is based on one barrel and two endcap air-core toroids, each consisting of eight superconducting coils arranged symmetrically in azimuth around the calorimeter. Three layers of precision tracking stations, consisting of drift tubes and cathode strip chambers, allow precise muon momentum measurement up to $|\eta| = 2.7$. Resistive plate and thin-gap chambers provide muon triggering capability up to $|\eta| = 2.4$.

The $pp$ collision data used in this analysis were recorded between March and August 2011 at a centre-of-mass energy of 7 TeV. After applying data quality requirements, the total integrated luminosity of the dataset used in this analysis is $2.08 \pm 0.08 \mathrm{fb}^{-1}$ [27]. Events are required to satisfy one of the single-lepton ($e$ or $\mu$) triggers. For electrons, the threshold on the transverse energy ($E_T$) is 20 GeV or 22 GeV depending on run periods, and for muons the threshold on the transverse momentum ($p_T$) is 18 GeV.

3 Event Preselection

The event preselection requires a primary vertex with at least three associated tracks with $p_T > 0.5$ GeV and exactly one electron and one muon of opposite charge. Electron candidates are selected from clustered energy deposits in the electromagnetic calorimeter with an associated track reconstructed in the ID. They are required to have $E_T > 25$ GeV and to lie inside the pseudorapidity regions $|\eta| < 1.37$ or $1.52 < |\eta| < 2.47$. Electrons are further required to satisfy a stringent set of identification requirements based on the calorimeter shower shape, track quality and track matching with the calorimeter energy cluster, referred to as ‘tight’ in Ref. [28]. Muons are reconstructed by combining tracks in the ID and MS with $p_T > 25$ GeV and $|\eta| < 2.4$. Electrons are rejected if they are located within a cone of $\Delta R = \sqrt{(\Delta \eta)^2 + (\Delta \phi)^2} = 0.2$ around a muon, where $\Delta \eta$ and $\Delta \phi$ are the pseudorapidity and azimuthal opening angle difference between the electron and muon.

To suppress backgrounds from $W/Z+\text{jets}$ and multijets, isolation requirements on tracks and calorimeter deposits are applied to the leptons. The scalar sum of the transverse momenta of tracks within a cone of $\Delta R = 0.2$ around the lepton must be less than 10% of the lepton’s $p_T$. Similarly, the transverse energy in the calorimeter within a cone of $\Delta R = 0.2$ around the lepton are required to be less than 15% of the lepton’s transverse energy. Corrections are applied to account for energy leakage and energy deposition inside the isolation cone due to additional $pp$ collisions.

Jets are reconstructed from calibrated clusters using the anti-$k_T$ algorithm [29] with a radius parameter of 0.4. Jet energies are calibrated using $E_{T,\text{jet}}$ and $\eta$-dependent correction factors based on Monte Carlo (MC) simulation and validated by test beam and collision data studies [30]. Only jets with $p_T > 30$ GeV and $|\eta| < 2.5$ are considered. If such a jet and an electron lie within $\Delta R = 0.2$ of each other, the jet is discarded.

The measurement of missing transverse momentum $E_T^{\text{miss}}$ is based on the transverse momenta of the electron and muon candidates, all jets, and all energy clusters with $|\eta| < 4.5$ not associated to such objects.

4 Background and Simulation

The SM processes that can produce an $e\mu$ signature are predominantly $t\bar{t}$, $Z/\gamma^* \rightarrow \tau\tau$, diboson, single top, $W/Z+\text{jets}$, $W/Z+\gamma$ and multijet events. All of these processes, except $W/Z+\text{jets}$ and multijet production, are estimated using Monte Carlo samples generated at $\sqrt{s} = 7$ TeV followed by a detailed GEANT4-based [32] simulation of the
ATLAS detector \cite{33}. To improve the agreement between data and simulation, selection efficiencies are measured in both data and simulation, and correction factors are applied to the simulation. Furthermore, the simulation is tuned to reproduce the calorimeter energy and the muon momentum scale and resolution. Top production is generated with MC@NLO \cite{34} for \( t\bar{t} \) and single top, the Drell-Yan process is generated with PYTHIA \cite{35}, and the diboson processes are generated with HERWIG \cite{36}. The \( W/Z + \gamma \) background comes from the \( W(\rightarrow \mu\nu)\gamma \) and \( Z(\rightarrow \mu\mu)\gamma \) processes, which is estimated using events generated with MADGRAPH \cite{37}. The simulation samples are normalized to cross sections with higher-order corrections applied.

The \( l\bar{l} \) signal processes are produced with the PYTHIA event generator \cite{36} with \( |\lambda_{131}\lambda_{231}| = |\lambda_{132}\lambda_{232}| = 0.05 \) and the value of \( m_t \) is varied from 95 GeV, which is the most stringent limit from previous experiments \cite{38}, to 1000 GeV. The central CTEQ6L1 \cite{39} parton distribution function (PDF) set is used. The LO cross section is 580 fb for \( m_t = 95 \text{ GeV} \) and 0.33 fb for \( m_t = 1000 \text{ GeV} \).

## 5 Data Analysis

The production of \( W/Z + \text{jets} \) and multijets can give rise to backgrounds due to jets misidentified as leptons or non-prompt leptons from heavy-quark decays in jets. These sources are referred to as fake background and are estimated from data. A looser lepton quality selection (called ‘loose’ lepton here) is defined for each lepton type in addition to the default tight quality selection. For loose muons, both the calorimeter and the track isolation requirements are removed. For loose electrons, the ‘loose’ electron identification criteria as defined in Ref. \cite{28} are used and the isolation requirements are also removed. The fake background is determined by weighting the events in the loose lepton sample by the likelihood that the event came from processes with at least one misidentified or non-prompt lepton. These weights are obtained by solving a 4 \times 4 matrix equation, constructed from the \( E_T - p_T \)-dependent probabilities for a prompt or fake/non-prompt lepton that passes the loose lepton requirement to also pass the tight lepton requirement. More details about the 4 \times 4 matrix method are given in Ref. \cite{7}.

The middle column of Table 1 gives the number of events observed in data, the estimated backgrounds, and expected number of signal events, assuming \( |\lambda_{131}\lambda_{231}| = |\lambda_{132}\lambda_{232}| = 0.05 \), with their combined systematic and statistical uncertainties for the preselected sample and the final selected sample. The number of signal and background events has been rounded.

### 6 Limit Setting

Since no excess is observed in data, the \( m_{e\mu} \) distribution in Figure 3 with a single bin for \( m_{e\mu} > 400 \text{ GeV} \) to reduce sensitivity to statistical fluctuations, is used to set limits on the production cross section of \( e\mu \) pairs through
The ATLAS Collaboration: Search for Lepton Flavour Violation in the $e\mu$ Continuum

Fig. 2. Observed distributions of dilepton invariant mass ($m_{e\mu}$), dilepton azimuthal opening angle ($\Delta\phi_{e\mu}$), $E_{\text{T}}^{\text{miss}}$ and number of jets after object selection (‘preselection’). The expected SM contributions, obtained as described in the text, with combined statistical and systematic uncertainties, are shown. In addition, the expected signal for $m_t = 95$ GeV is overlaid. For each case, a plot of the ratio of observed events to the expected background is shown. The error bars on these points represent the statistical errors on the data points and the hashed boxes represent the total error (statistical and systematic) on the expected background.

t-channel exchange of $t$ in RPV SUSY models. A modified frequentist approach, using a binned log-likelihood ratio (LLR) of the signal-plus-background hypothesis to the background only hypothesis, is used to set the 95% confidence level (CL) upper limits. Confidence levels, $\text{CL}_{s+b}$ and $\text{CL}_b$, are defined by integrating the normalized probability distribution of LLR values from the observed LLR value to infinity for the two hypotheses. Since no data excess is observed, the production cross section is excluded at 95% CL when $1 - \text{CL}_{s+b}/\text{CL}_b \geq 0.95$. The limits take into account systematic uncertainties by convolving the Poisson probability distributions for signal and background with the probability distributions for the corresponding uncertainty, which are assumed to be Gaussian.

The upper limit on the production cross section for $pp \to e\mu X$ through the $t$-channel exchange of a $t$ at 95% CL is shown in Fig. 4(a). For a $t$ with mass of 95 GeV (1000 GeV), the limit on the production cross section is 170 (30) fb which is in agreement with the expected limit of $180^{+80}_{-60} (30^{+11})$ fb. The theoretical cross section for $|\lambda^{131}_{13} \lambda^{231}_{23}| = |\lambda^{132}_{12} \lambda^{232}_{23}| = 0.05$ is also shown to illustrate the sensitivity.

The fraction of events produced by the $d\bar{d} \to e\mu$ ($s\bar{s} \to e\mu$) process is predicted to be $f_{d\bar{d}} = 0.72$ ($f_{s\bar{s}} = 0.28$) using the PYTHIA generator with the central CTEQ6L1 PDF set and with $m_t = 95$ GeV. The cross section for the signal process is hence proportional to the PDF-weighted sum of the RPV couplings, which is $f_{d\bar{d}} \times |\lambda^{131}_{13} \lambda^{231}_{23}|^2 + f_{s\bar{s}} \times |\lambda^{132}_{12} \lambda^{232}_{23}|^2$. The cross section limits set above can be interpreted as a limit on the plane spanned by the sum of couplings and $m_t$. The resulting two-dimensional 95% confidence limit is shown in Fig. 4(b).
The ATLAS Collaboration: Search for Lepton Flavour Violation in the $e\mu$ Continuum

7 Conclusion

This paper presents a search for LFV interactions in the $e\mu$ continuum, as modelled by the $t$-channel exchange of a scalar top quark, using 2.1 fb$^{-1}$ of data collected by the ATLAS detector in $\sqrt{s} = 7$ TeV $pp$ collisions at the LHC. The data are found to be consistent with the SM predictions. Upper limits are set on the production cross section for $pp \to e\mu X$ through the $t$-channel exchange of a $\tilde{t}$. A two dimensional limit in the plane of the weighted sum of couplings vs $m_\tilde{t}$ is also obtained.
