We study the initial-state-radiation processes $e^+ e^- \rightarrow K^+ K^- \pi^+ \pi^- \gamma$ and $e^+ e^- \rightarrow K^+ K^- \phi \phi \gamma$ using an integrated luminosity of 232 fb$^{-1}$ collected at the $Y(4S)$ mass with the BABAR detector at SLAC. Even though these reactions are dominated by intermediate states with excited kaons, we are able to study for the first time the cross section for $e^+ e^- \rightarrow \phi(1020)f_0(980)$ as a function of center-of-mass energy. We observe a structure near threshold consistent with a $1^{--}$ resonance with mass $m = 2.175 \pm 0.010 \pm 0.015$ GeV$/c^{2}$ and width $\Gamma = 58 \pm 16 \pm 20$ MeV. We observe no $Y(4260)$ signal and set a limit of $\mathcal{B}_{Y \rightarrow \phi \phi \pi^+ \pi^-} \cdot \Gamma_{\pi \gamma} < 0.4$ eV (90% confidence level), which excludes some models.

DOI: 10.1103/PhysRevD.74.091103

The nature of the $Y(4260)$ resonance, which BABAR recently discovered [1] through its production via initial-state radiation (ISR) in $e^+ e^-$ annihilations and its decay into $J/\psi \pi^+ \pi^-$, remains unclear. It is well above threshold for the $D^{(*)}D^{(*)}$ decays expected for a wide charmonium state, but no peak is observed in the total cross section $e^+ e^- \rightarrow$ hadrons in this mass region. Some models [2] predict a large branching fraction for $Y(4260)$ into $\phi \pi \pi$. Moreover, the rich spectroscopy of the $J=0$ final state motivates a thorough investigation of the analogous $\phi \pi \pi$ state.

In this paper we update our previous analysis with ISR of $e^+ e^- \rightarrow K^+ K^- \pi^+ \pi^- [3]$. We include more data and relax the selection criteria, resulting in a fivefold increase in the number of selected events. We obtain an improved $e^+ e^- \rightarrow K^+ K^- \pi^+ \pi^-$ cross section measurement over a wide range of effective $e^+ e^-$ center-of-mass (C.M.) energies, and perform the first studies of the $\phi \pi^+ \pi^-$, $f_0(980)K^+K^-$ and $\phi f_0$ intermediate states. We also present the first measurements of the $e^+ e^- \rightarrow K^+ K^- \pi^0 \pi^0$ cross section and its $\phi f_0$ component.

We use data corresponding to an integrated luminosity of 232 fb$^{-1}$ recorded by the BABAR detector [4] on and off the $Y(4S)$ resonance. Charged-particle tracking is provided by a five-layer silicon vertex tracker (SVT) and a 40-layer drift chamber (DCH) in a 1.5 T axial magnetic field. Photon and electron energies are measured in a CsI(Tl) electromagnetic calorimeter (EMC). Charged particles are identified by specific ionization in the SVT and DCH, and an internally reflecting ring-imaging Cherenkov detector (DIRC).

We use a simulation package developed for radiative processes that generates hadronic final states following Ref. [5], multiple soft photons from the initial state using a structure-function technique [6,7], and photons from the final-state particles using PHOTOS [8]. We generate $K^+ K^- \pi^+ \pi^-$ final states both according to phase space and with a model that includes the $\phi(1020)$ to $K^+ K^-$ and $f_0(980)$ to $\pi^+ \pi^-$ channels. We pass the events through a detector simulation [9], and reconstruct them in the same way as we do the data. We generate a number of backgrounds with this package, including the ISR processes $e^+ e^- \rightarrow \pi^+ \pi^- \pi^+ \pi^- \gamma, \pi^+ \pi^- \pi^0 \pi^0 \gamma, \phi \eta \gamma, \phi \pi^0 \gamma$ and $\pi^+ \pi^- \pi^0 \gamma$, and we also study $e^+ e^- \rightarrow q\bar{q}$ events generated by JETSET [10], $e^+ e^- \rightarrow \tau^+ \tau^-$ by KORALB [11], and $Y(4S)$ decays using our own generator [12].

The initial selection of events with a high-energy photon recoiling against a set of charged particles and photons is described in Refs. [3,13]. Here we accept all charged tracks that extrapolate to the interaction region, and photon candidates with an EMC energy greater than 30 MeV. The reconstructed vertex of the set of charged tracks is used as the point of origin for all photons.

For each four-track event with one or two identified $K^\pm$, we perform a set of three-constraint kinematic fits (see Ref. [13]). We assume the photon with the highest C.M. energy to be from ISR, and the fits use its direction, along with the four-momenta and covariance matrices of the initial $e^+ e^-$ and the reconstructed tracks. A fit using the $\pi^+ \pi^- \pi^+ \pi^-$ hypothesis returns a $\chi^2_{\pi\pi}$. If the event contains an identified $K^+$ and $K^-$, we fit to the $K^+ K^- \pi^+ \pi^-$ hypothesis and require $\chi^2_{KK\pi\pi} < 30$. For events with one identified kaon, we perform fits with each of the two oppositely charged tracks given the kaon hypothesis, and the combination with the lowest $\chi^2_{K\pi\pi\pi}$ is retained if it is lower than 30 and $\chi^2_{\pi\pi} > \chi^2_{KK\pi\pi\pi}$.

For the events with two tracks, both identified as charged kaons, and five or more photon candidates, all non-ISR photons are paired, and combinations lying within $35$ MeV$/c^2$ of the $\pi^0$ mass are considered $\pi^0$ candidates. We perform a six-constraint fit to each set of two non-overlapping $\pi^0$ candidates plus the ISR photon and the $K^+$ and $K^-$ tracks, and the combination with the lowest $\chi^2_{KK\pi0\pi0}$ is retained if $\chi^2_{KK\pi0\pi0} < 50$. To suppress ISR $K^+ K^- \pi^0$ and $K^+ K^- \eta$ events, in which photons from an energetic $\pi^0$ or $\eta$ combine with soft background clusters to form two $\pi^0$ candidates, we reject events with large differences between the two photon energies in both $\pi^0$ candidates. The fitted three-momenta for each charged track and photon are used in further kinematical calculations.

We consider three types of backgrounds. The first, which peaks at low values of $\chi^2$, is due to non-ISR events, and is dominated by $e^+ e^- \rightarrow q\bar{q}$ events with a hard $\pi^0$ producing a fake ISR photon. To evaluate this background, we use simulated mass and $\chi^2$ distributions normalized to data events in which the ISR photon combines with another

cluster to form a $\pi^0$ candidate. The second type of background, due to ISR $e^+ e^- \rightarrow \pi^+ \pi^- \pi^+ \pi^-$ events with misidentified $\pi^\pm$, also contributes at low $\chi^2$ values. We derive reliable estimates of their contributions from the known cross sections [3]. The third type of background comprises all remaining background sources and is estimated from the control regions $30 < \chi^2_{KK\pi\pi} < 60$ and $50 < \chi^2_{KK\pi\pi} < 100$, as detailed in Refs. [3,13]. We subtract these backgrounds, about 8%–10% (15%–20%) total contribution, from the selected $K^+ K^- \pi^+ \pi^-$ ($K^+ K^- \pi^0 \pi^0$) events.

We measure the track-finding efficiency from the data, and measure the kaon identification efficiency from a clean sample of ISR $e^+ e^- \rightarrow \phi \rightarrow K^+ K^-$ events to a precision of 2.0%, a fourfold improvement over our previous result [3]. The $\pi^0$ reconstruction efficiency is determined from ISR $e^+ e^- \rightarrow \omega \pi^0\gamma \rightarrow \pi^+ \pi^- \pi^0\pi^0\gamma$ events and the method described in Ref. [13]. The above procedures allow us to correct the efficiency obtained from the Monte Carlo (MC) simulation. In Fig. 1 we show the cross sections for the two processes, calculated by dividing the background-subtracted yield in each bin by the efficiency and the ISR luminosity [3]. The errors are statistical only. The $e^+ e^- \rightarrow K^+ K^- \pi^+ \pi^-$ cross section [Fig. 1(a)] is consistent with both the direct measurement by DM1 [14] and our previous measurement [3], but is far more precise. In addition to the sharp $J/\psi$ peak, wider structures are visible near 1.8 GeV, 2.2 GeV and possibly 2.4 GeV. The $e^+ e^- \rightarrow K^+ K^- \pi^0\pi^0$ cross section [Fig. 1(b)] shows the same general features, including a $J/\psi$ peak and a steep drop around 2.2 GeV. The total systematic uncertainty in the $K^+ K^- \pi^+ \pi^-(\pi^0\pi^0)$ cross section ranges from 7% (10%) at threshold to 9% (15%) at high $E_{C.M.}$.

As seen previously [3], there is a rich substructure in the $e^+ e^- \rightarrow K^+ K^- \pi^+ \pi^-$ process, dominated by the $K^{(*)}(892)K\pi$ intermediate state, but with large signals from the $K_1(1270)$, $K_{1}^{*}(1430)$ and $K_1(1400)$ resonances. The $e^+ e^- \rightarrow K^+ K^- \pi^0\pi^0$ process is also dominated by the $K^{\pm}(892)K^{\mp} \pi^0$ intermediate state. Understanding these contributions via a partial wave analysis is outside the scope of this paper.

Here we concentrate on events with an intermediate $\phi(1020)$ and/or $f_0(980)$ state. Figure 2 shows scatter plots of $m(\pi^+ \pi^-)$ or $m(\pi^0\pi^0)$ versus $m(K^+ K^-)$ for the selected events (including backgrounds) in the data. A $\phi \rightarrow K^+ K^-$ band is visible in both cases, as well as a concentration of events indicating correlated production of $\phi$ and $f_0$. A horizontal $\rho(770)$ band is visible for the charged mode only, and is due to $K_1 \rightarrow K\rho$ decays. Most of the $K^*$ intermediate states are outside the bounds of these plots. Selecting $\phi$ events with $[m(K^+ K^-) - 1020 \text{MeV}/c^2] < 10 \text{MeV}/c^2$, and subtracting events with $10 < [m(K^+ K^-) - 1020 \text{MeV}/c^2] < 20 \text{MeV}/c^2$ [see Figs. 3(a) and 3(c)] and MC simulated backgrounds, we obtain the $\phi$-associated $m(\pi\pi)$ distributions shown in Figs. 3(b) and 3(d). Clear $f_0(980)$ signals are visible in both cases, and there is an indication of $f_2(1270) \rightarrow \pi^+ \pi^-$. The histogram in Fig. 3(b) is the result of a simulation that includes $f_0(600)$, $f_0(980)$ and a small fraction of $f_2(1270)$ resonances and describes the general features of the distribution. The curve in Fig. 3(d) shows a fit of two Breit-Wigner functions corresponding to the $f_0(600)$ and $f_0(980)$ with the relative phase set to $\pi$; events with

![FIG. 1 (color online). The (a) $e^+ e^- \rightarrow K^+ K^- \pi^+ \pi^-$ and (b) $e^+ e^- \rightarrow K^+ K^- \pi^0\pi^0$ cross sections as a function of $e^+ e^-$ C.M. energy. The direct measurements by DM1 [14] are shown for comparison as open circles. Only statistical errors are shown.](091103-5)
FIG. 2 (color online). The scatter plots of the reconstructed (a) \(m(K^+K^-)\) and (b) \(m(\pi^0\pi^0)\) versus \(m(K^+K^-)\) for selected events in the data. The vertical (horizontal) lines bound a \(\phi\) \([f_0(980)]\) signal region.

FIG. 3 (color online). The \(m(K^+K^-)\) projections for the (a) \(K^+K^-\pi^+\pi^-\) and (c) \(K^+K^-\pi^0\pi^0\) candidates in the data. The vertical lines delimit \(\phi\) signal and sideband regions. (b, d) \(m(\pi\pi)\) distribution for events in the \(\phi\) signal region of (a, c) minus that for events in the sidebands. The curves (histogram) represent the results of the fits (simulation) described in the text.
\( m(\pi^0\pi^0) < 0.45 \text{ GeV}/c^2 \) are dominated by background-subtraction uncertainties and are not used in the fit. The fitted \( f_0 \) parameters are consistent with PDG [15] values. Figure 4 shows the \( m(K^+K^-\pi^\pm\pi^-) \) distributions in the charmonium region for events with \( m(K^+K^-) \) in the \( \phi \) signal and sideband regions. There is a strong \( J/\psi \) signal in both samples; from the signal-sideband differences of 103 \( \pm 12 \) and 23 \( \pm 6 \) events, we calculate

\[
\mathcal{B}_{J/\psi \to \phi \pi^+\pi^-} \cdot \Gamma_{J/\psi} \cdot \mathcal{B}_{\phi \to K^+K^-} = (2.61 \pm 0.30 \pm 0.18) \text{ eV}
\]

and the first measurement of

\[
\mathcal{B}_{J/\psi \to \phi \pi^+\pi^-} \cdot \Gamma_{J/\psi} \cdot \mathcal{B}_{\phi \to K^+K^-} = (1.54 \pm 0.40 \pm 0.16) \text{ eV}.
\]

We also observe 10 \( \pm 4 \) \( \psi(2S) \to \phi \pi^+\pi^- \) decays, from which we determine

\[
\mathcal{B}_{\psi(2S) \to \phi \pi^+\pi^-} \cdot \Gamma_{\psi(2S)} \cdot \mathcal{B}_{\phi \to K^+K^-} = (0.28 \pm 0.11 \pm 0.02) \text{ eV}.
\]

There is no signal for \( Y(4260) \to \phi \pi^+\pi^- \). In the region \( |m(\phi \pi^+\pi^-) - m(Y)| < 0.1 \text{ GeV}/c^2 \) we find 10 events, and, assuming a uniform distribution, we estimate 9.2 background events from the 3.8–5.0 \text{ GeV}/c^2 region. This corresponds to upper limits of 5.0 events and

\[
\mathcal{B}_{Y \to \phi \pi^+\pi^-} \cdot \Gamma_{Y} < 0.4 \text{ eV}
\]

at the 90\% confidence level, which is in agreement with the upper limit obtained by CLEO [16] and is well below our analogous measurement \( \mathcal{B}_{Y \to J/\psi \pi^+\pi^-} \cdot \Gamma_{Y} = (5.5 \pm 1.1 \pm 0.8) \text{ eV} \). This excludes models (e.g. [2]) in which these two \( Y(4260) \) branching fractions are comparable.

We now consider the quasi-two-body intermediate state \( \phi f_0 \). In each 25 \text{ MeV}/c^2 (40 \text{ MeV}/c^2) bin of \( m(K^+K^-\pi^\pm\pi^-) \) we select \( K^+K^-\pi^+\pi^- \) (\( K^+K^-\pi^0\pi^0 \)) events with \( m(\pi^+\pi^-) \) (\( m(\pi^0\pi^0) \)) in the 0.85–1.1 \text{ GeV}/c^2 region and fit their \( m(K^+K^-) \) distribution to extract the number of events with a true \( \phi \). These are shown in Fig. 5 with about 700 events for the \( K^+K^-\pi^+\pi^- \) channel and about 120 events for the \( K^+K^-\pi^0\pi^0 \) channel; there is a contribution of about 10\% from \( e^+e^- \to \phi \pi\pi \) events where the pion pair is not produced through the \( f_0 \). Both distributions show the sharp rise from threshold as expected for a pair of relatively narrow resonances, and a slow, smooth decrease at high \( E_{CM} \), with signals for \( J/\psi \) and \( \psi(2S) \) in Fig. 5(a). Both also show a resonancelike structure at about 2.15 \text{ GeV}/c^2. There are no known meson resonances with \( J = 0 \) near this mass.

Dividing by the efficiency, ISR luminosity, \( \mathcal{B}_{\phi \to K^+K^-} = 0.491 [15] \), and \( \mathcal{B}_{\psi \to \pi^+\pi^- (\pi^0\pi^0)} = 2/(3/(1/3)) \), we obtain the two consistent measurements of the \( e^+e^- \to \phi f_0 \) cross section shown in Fig. 6 (including about 10\% \( \phi \pi\pi \) contribution). We use the following function of \( s = E_{CM}^2 \):

\[
\sigma(s) = \frac{P(s)}{P(m^2_{ee})} \cdot \frac{1}{m^2_{ee} - s - i\sqrt{s} \Gamma_{ee}} \left\lvert A_m e^{-i\phi_m} + \frac{\sqrt{\sigma_0 m_\perp} \Gamma_{ee}}{m^2_{ee} - s - i\sqrt{s} \Gamma_{ee}} \right\rvert^2, \quad (1)
\]

\[
A_m(s) = N_{nr} \cdot (1 - e^{-\mu/\sqrt{s}}) \cdot (1 + a_2 \mu + a_3 \mu^2),
\]

\[
\mu = \sqrt{s} - m_0, \quad P(s) = \sqrt{1 - m^2_0/s}, \quad (2)
\]

where \( N_{nr} \) normalizes the amplitude of the nonresonant

---

**FIG. 4 (color online).** The (a) \( m(K^+K^-\pi^+\pi^-) \) and (b) \( m(K^+K^-\pi^0\pi^0) \) distributions in the charmonium region for events in the \( \phi \) signal (open histogram) and sideband (shaded histogram) regions. The vertical lines indicate the range used for the \( Y(4260) \) search.
spectrum, $\sigma_0$ is a peak cross section for the hypothesized resonance, and $m_x$, $\Gamma_x$ and $-\psi_x$ are the mass, total width and relative phase of the nonresonant amplitude to the standard Breit-Wigner amplitude. The factor $P(s)$ gives a good approximation of the two-body phase space factor for particles with similar masses; both the $\phi(1020)$ and $f_0(980)$ have small but finite widths, and our selection of $m(\pi\pi) > 0.85$ GeV/c$^2$ defines an effective minimum mass, $m_0 = 1.8$ GeV/c$^2$. The form of $A_{y_{\phi}}$ is determined from a simulation that takes the $\phi$ and $f_0(980)$ line shapes into account. A very sharp exponential cutoff (parameter $a_1$) is needed to describe the simulation well, but does not affect the spectrum well above threshold. There is no theoretical prediction for the form at high $s$, other than that, in the absence of resonances, it should fall smoothly with increasing $s$. A second order polynomial (parameters $a_2$ and $a_3$) describes the simulation, so we fit Eq. (2) to the data, floating $N_{_{W}}, a_1$, $a_2$ and $a_3$. The result without a resonant component is shown as the dashed curve in Fig. 6. The $\chi^2 = 80.5/(56 - 5)$ has confidence level $P(\chi^2_0) = 0.0053$, and the fitted parameter values are close to those from the simulation; it is unlikely that a simple, smooth threshold curve can accommodate the data.

Including a single resonance [Eq. (1)], we obtain a good fit with $\chi^2 = 37.6/(56 - 9)$ [$P(\chi^2) = 0.84$], shown as the solid line in Fig. 6. The fitted resonance parameter values are

\begin{align*}
\sigma_0 & = 0.13 \pm 0.04 \pm 0.02 \text{ nb}, \\
m_x & = 2.175 \pm 0.010 \pm 0.015 \text{ GeV/c}^2, \\
\Gamma_x & = 0.058 \pm 0.016 \pm 0.020 \text{ GeV/c}^2 \quad \text{and} \\
\psi_x & = -0.57 \pm 0.30 \pm 0.20 \text{ rad}.
\end{align*}

The first error is statistical and the second is systematic. Monte Carlo simulations show that the probability of such a signal arising by chance is less than $10^{-3}$. The modestly negative value of $\psi_x$ provides constructive interference below the resonance peak and destructive interference above it, in accordance with the data. Variations in the resonance parameters are used to estimate the systematic errors. The fit of the mass spectra in Figs. 5(a) and 5(b)
with Eq. (1) with normalization to the number of events under the Breit-Wigner curve gives $170 \pm 63$ and $31 \pm 15$ events for $\pi^+\pi^-$ and $\pi^0\pi^0$, respectively. Note that the observed structure is close to the $\Lambda\Lambda$ production threshold at 2.23 GeV/$c^2$ and the opening of this channel may also contribute to the $\phi f_0$ cross section.

We perform a number of systematic checks. Treating selected $K^+ K^- K^+ K^-$ and $\pi^+\pi^-\pi^+\pi^-$ events as signal (replacing two kaon masses by pion masses, or vice versa), we observe no structure. Selecting $K^*(892)K\pi$ events, which have little kinematic overlap with $\phi f_0(980)$, we see no structure. Excluding the dominant $K^*(892)K\pi$ intermediate states and selecting events with $m(\pi^+\pi^-)$ in the range 0.6–0.85 GeV/$c^2$ for the charged mode, we observe structure at 2.15 GeV/$c^2$ with a similar yield. Because of the many overlapping intermediate states, we cannot perform a quantitative measurement. This will be the subject of future investigation. Events with no $f_0(980)$ candidate do not exhibit a structure in the $K^+ K^- \pi^0\pi^0$ mode. We conclude that the new structure decays to $\phi f_0(980)$ with a relatively large branching fraction. We estimate

$$\mathcal{B}_{\phi \rightarrow \phi f_0}, \frac{\Gamma_{\phi f_0}}{2\pi C} = (2.5 \pm 0.8 \pm 0.4) \text{ eV},$$

where we fit the product $\Gamma_{\phi} \sigma_0$ to reduce correlations, and the conversion constant $C = 0.389 \text{ mb/(GeV/c)}^2$.

In summary, we present the most precise measurements of the cross sections for $e^+e^- \rightarrow K^+K^-\pi^+\pi^-$ and $e^+e^- \rightarrow K^+K^-\pi^0\pi^0$ from threshold to 4.5 GeV. In the $\phi\pi\pi$ channels, we observe the $J/\psi$ and $\psi(2S)$ but not the $Y(4260)$. In the $\phi f_0$ channel, we observe a new resonance-like structure, which might be interpreted as an $s\bar{s}$ analogue of the $Y(4260)$, or as an $s\bar{s}s\bar{s}$ state that decays predominantly to $\phi f_0(980)$.

We are grateful for the excellent luminosity and machine conditions provided by our PEP-II colleagues, and for the substantial dedicated effort from the computing organizations that support BABAR. The collaborating institutions wish to thank SLAC for its support and kind hospitality.
