We present a study of the decays $B^0 \to D^{(*)0} \bar{K}^{(*)0}$ using a sample of $226 \times 10^6$ $Y(4S) \to B\bar{B}$ decays collected with the BABAR detector at the PEP-II asymmetric-energy $e^+e^-$ collider at SLAC. We report evidence for the decay of $B^0$ and $B^0$ mesons to the $D^{(*)0}K_S^0$ final state with an average branching fraction

$$\mathcal{B}(B^0 \to D^{(*)0}K_S^0) = \frac{\mathcal{B}(B^0 \to D^{(*)0}K_S^0) + \mathcal{B}(B^0 \to D^{(*)0}K_S^0)/2}{2} \approx (3.6 \pm 1.2 \pm 0.3) \times 10^{-5}.$$ 

Similarly, we measure $\mathcal{B}(B^\prime \to D^{(*)0}K_S^0) = \frac{\mathcal{B}(B^\prime \to D^{(*)0}K_S^0) + \mathcal{B}(B^\prime \to D^{(*)0}K_S^0)/2}{2} \approx (5.3 \pm 0.7 \pm 0.3) \times 10^{-5}$ for the $D^{(*)0}K_S^0$ final state. We measure $\mathcal{B}(B^0 \to D^{(*)0}K_S^0) = (4.0 \pm 0.7 \pm 0.3) \times 10^{-5}$ and set a $90\%$ confidence level upper limit $\mathcal{B}(B^0 \to D^{(*)0}K_S^0) < 1.1 \times 10^{-5}$. We determine the upper limit for the decay amplitude ratio $|\mathcal{A}(B^0 \to D^{(*)0}K_S^0)/\mathcal{A}(B^0 \to D^{(*)0}K_S^0)|$ to be less than 0.4 at the $90\%$ confidence level.

With the discovery of $CP$ violation in the decays of neutral $B$ mesons [1] and the precise measurement [2] of the angle $\beta$ of the Cabibbo-Kobayashi-Maskawa (CKM) Unitarity Triangle [3], the experimental focus has shifted towards over-constraining the unitarity triangle through precise measurements of $|V_{ub}|$ and the angles $\alpha$ and $\gamma$. The angle $\gamma$ is $\arg(-V_{ts}V_{td}^*/V_{cb}V_{cd}^*)$ and $V_{ij}$ are CKM matrix elements. Several methods have been suggested and explored to measure $\gamma$ with small uncertainties [4], but they all require large samples of $B$ mesons not yet available. The decay modes $B^0 \to D^{(*)0}\bar{K}$ offer a new approach for the determination of $\sin(2\beta + \gamma)$ from the measurement of time-dependent $CP$ asymmetries in these decays [5]. The $CP$ asymmetry appears as a result of the interference between two diagrams leading to the same final state $D^{(*)0}K_S^0$ (Fig. 1). A $B^0$ meson can either decay via a $b \to c$ quark transition to the $D^{(*)0}\bar{K}$ ($\bar{K} \to K_S^0$) final state, or oscillate into a $B^0$ which then decays via $\bar{b} \to \bar{u}$ transition to the $D^{(*)0}\bar{K}$ ($\bar{K} \to K_S^0$) final state [6]. The $B^0B^\prime$ oscillation provides the weak phase $2\beta$ and the relative weak phase between the two decay diagrams is $\gamma$.

The sensitivity of this method [5] depends on the rates for these decays and the ratio of the decay amplitudes. The branching fractions $\mathcal{B}(B^0 \to D^{(*)0}\bar{K})$ can be estimated from the measured color-suppressed decays $B^0 \to D^{(*)0}\pi^0$ [7] to be approximately $\mathcal{B}(B^0 \to D^{(*)0}\bar{K}) = \sin^2\theta_c\mathcal{B}(B^0 \to D^{(*)0}\pi^0) \approx O(10^{-5})$, where $\theta_c$ is the Cabibbo angle and $\sin\theta_c = 0.22$. The Belle Collaboration has observed the $B^0 \to D\bar{K}$ decays with branching fractions consistent with this naive expectation [8]. The time-dependent $CP$ asymmetries in $B^0 \to D^{(*)0}\bar{K}$ decays are proportional to $r_B^{(s)} \cdot \sin(2\beta + \gamma \pm \delta)/(1 + r_B^{(s)})^2$, where $r_B^{(s)} = |\mathcal{A}(B^0 \to D^{(*)0}\bar{K})/\mathcal{A}(B^0 \to D^{(*)0}\bar{K})|$ and $\delta$ is a relative strong phase which depends on the specific final state. Higher values of $r_B^{(s)}$ lead to larger interference between the $b \to c$ and $b \to u$ processes and thus increased sensitivity to the angle $\gamma$. In the standard model $r_B^{(s)} = f \cdot |V_{ub}V_{cs}^*/|V_{cb}V_{us}|$, where the factor $f$ accounts for the difference in the strong interaction dynamics between the $b \to c$ and $b \to u$ processes. There are no theoretical calculations or experimental constraints on $f$.

In $B^0 \to D^{(*)0}\bar{K}$ ($\bar{K} \to K_S^0$) decays the strangeness content of the $\bar{K}$ is hidden and one cannot distinguish between $B^0 \to D^{(*)0}\bar{K}$ and $B^0 \to D^{(*)0}K^0$. Therefore a direct determination of $r_B^{(s)}$ from the measured rates is not feasible. In the remainder of this paper we refer to these decays as $B^0 \to D^{(*)0}\bar{K}$. Insight into the $B^0$ decay dynamics affecting $r_B^{(s)}$ can be gained by measuring a similar amplitude ratio $\tilde{r}_B^{(s)} = |\mathcal{A}(B^0 \to D^{(*)0}\bar{K})/\mathcal{A}(B^0 \to D^{(*)0}\bar{K})|$ using the self-tagging decay $K^{*0} \to K^-\pi^+$. The $B^0 \to D^{(*)0}\bar{K}$ and $B^0 \to D^{(*)0}K^0$ decays are distinguished by the correlation between the charges of the kaons produced in the decays of the neutral $D$ and the $K^{*0}$. In the former decay the two kaons in the final state must have the same charge, while in the latter they are oppositely charged. This charge correlation in the final state is diluted by the presence of the doubly-Cabibbo-suppressed decays $D^+ \to K^+\pi^-, K^+\pi^-\pi^0,$ and $K^+\pi^+\pi^-\pi^+$. The ratio $\tilde{r}_B^{(s)}$ is related to the experimental observables $\mathcal{R}_i$ defined as

$$\mathcal{R}_i = \frac{\Gamma(B^0 \to K^+X^-)\mathcal{B}(K^+X^-)}{\Gamma(B^0 \to K^-X^+)\mathcal{B}(K^-X^+)} = \tilde{r}_B^{(s)} + r_{D_i}^2 + 2\tilde{r}_B^{(s)}r_{D_i}\cos(\gamma + \delta_i), \quad (1)$$

where

$$X_i^\pm = \pi^\pm, \pi^-\pi^0, \pi^+\pi^-\pi^+, \quad (2)$$

and

$$r_{D_i} = \frac{|\mathcal{A}(D^0 \to K^+X_i^-)|}{|\mathcal{A}(D^0 \to K^-X_i^+)|}. \quad (3)$$

FIG. 1. The decay diagrams for the $b \to c$ transition $B^0 \to D^{(*)0}\bar{K}^{(*)0}$ and the $\bar{b} \to \bar{u}$ transition $B^0 \to D^{(*)0}K^{(*)0}$. 

B. AUBERT et al.

PHYSICAL REVIEW D 74, 031101(R) (2006)
and $\delta_B$ and $\delta_{D_1}$ are strong phase differences between the two $B$ and $D_1$ decay amplitudes, respectively. The values of $r_{D_1}$ have been measured to be $r_{D_1 \to K^-} = 0.060 \pm 0.002$, $r_{D_1 \to \pi^+ \pi^-} = 0.066 \pm 0.010$, and $r_{D_1 \to K^- \pi^+ \pi^-} = 0.065 \pm 0.010$ \cite{9}.

We present herein measurements of the branching fractions $B(B_0 \to D^{(*)0}K^{(*)0})$ and $B(B_0 \to D^{(*)0}K^{(*)0})$, evidence for the decay $B^0 \to D^{(*)0}K^{(*)0}$, a $90\%$ confidence level (C.L.) upper limit for the branching fraction of the $b \to u$ transition $B^0 \to D^{(*)0}K^{(*)0}$, and a limit for the ratio $r_B$.

These results are based on a sample of $226 \times 10^6 Y(4S) \to B\bar{B}$ decays collected with the BABAR detector between 1999 and 2004 at the PEP-II asymmetric-energy $e^+e^-$ collider operating at the $Y(4S)$ resonance. The properties of the continuum $e^+e^- \to q\bar{q}(q = u, d, s, c)$ background events are studied with a data sample of $11.9 \text{ fb}^{-1}$ recorded at an energy $40 \text{ MeV}$ below the $Y(4S)$ resonance. The BABAR detector has been described in detail elsewhere \cite{10}. Detector components relevant for this analysis are summarized here. Trajectories of charged particles are measured in a spectrometer consisting of a five-layer silicon vertex tracker (SVT) and a 40-layer drift chamber (DCH) operating in a 1.5 T axial magnetic field. Charged particles are identified as pions or kaons using information from a detector of internally reflected Cherenkov light, as well as measurements of energy loss from ionization ($dE/dx$) in the SVT and the DCH. Photons are detected using an electromagnetic calorimeter composed of 6580 thallium-doped CsI crystals. We use a Monte Carlo simulation of the BABAR detector based on GEANT4 \cite{11} to validate the analysis procedure and to study the backgrounds. Simulated events are generated with the EvtGen \cite{12} event generator.

We reconstruct the decays $B^0 \to D^0 \bar{K}^0$, $D^{(*)0} \bar{K}^0$, $D^{(*)0} K^{(*)0}$, and $D^{(*)0} K^{(*)0}$ in the decay chains: $D^{(*)0} \to D^0 \pi^0$; $D^0 \to K^- \pi^+$, $K^- \pi^+ \pi^0$, and $K^- \pi^- \pi^+ \pi^0$; $K^0 \to K^0 \to \pi^+ \pi^-$; $K^0 \to K^0 \to \pi^+ \pi^- \pi^+$; and $\pi^0 \to \gamma \gamma$. For each $B$ decay channel the optimal selection criteria are determined by maximizing the ratio $N_3/\sqrt{N_3 + N_{B'}}$, where $N_3$ and $N_{B'}$ are, respectively, the expected signal and background yields estimated from samples of simulated events. A large sample of the more abundant $B^+ \to D^0 \pi^+$ decays, in which the $D^0$ decays to the $K^- \pi^+$, $K^+ \pi^+ \pi^0$, or $K^+ \pi^+ \pi^+ \pi^-$ final states, is used as a calibration sample to measure efficiencies and experimental resolutions for the selection variables.

Well reconstructed charged tracks are used to reconstruct $D^0$ and $K^{(*)0}$ candidates. The $K^\pm$ candidates must satisfy a set of kaon identification criteria. These identification criteria have an average efficiency of about 90\%, while the probability of a pion to be misidentified as a kaon varies between a few percent and 15\%. Photons are reconstructed from energy deposition clusters in the electromagnetic calorimeter consistent with photon showers, and are required to have an energy greater than $30 \text{ MeV}$. We select $\pi^0$ candidates from pairs of photon candidates by requiring their invariant mass to be in the interval $115 \text{ MeV}/c^2 < m(\gamma\gamma) < 150 \text{ MeV}/c^2$.

The $K_S^0$ candidates are selected from pairs of oppositely charged tracks with invariant mass within $7 \text{ MeV}/c^2$ (\~2$\sigma$) of the nominal $K_S^0$ mass. The displacement of the $K_S^0$ decay vertex from the interaction point, in the plane perpendicular to the beam axis, divided by its estimated uncertainty must be greater than 2. The $K^{(*)0}$ candidates are selected from pairs of oppositely charged $K^+$ and $\pi^-$ tracks, with invariant mass within $50 \text{ MeV}/c^2$ of the nominal $K^{(*)0}$ mass. The polarization of the $K^{(*)0}$ in the $B^0$ decay is used to reject backgrounds by requiring $|\cos \theta_h| > 0.4$, where the helicity angle $\theta_h$ is defined as the angle between the direction of the $K^{(*)0}$ in the $B^0$ meson rest frame and the direction of its daughter $K^+$ in the $K^{(*)0}$ rest frame. For $B^0 \to D^0 K^{(*)0}$ and $B^0 \to D^0 K^{(*)0}$ signal candidates, $\theta_h$ follows a $\cos \theta_h$ distribution, while the combinatorial background is distributed uniformly.

We reconstruct $D^0$ candidates in the $K^- \pi^+$ and $K^- \pi^+ \pi^- \pi^+$ decay modes by combining charged tracks, retaining combinations with an invariant mass within $2\sigma$ of the nominal $D^0$ mass $m_{D^0}$. In the $D^0 \to K^- \pi^+ \pi^0$ selection, the $\pi^0$ candidates are required to have a center-of-mass (CM) momentum $p^\pi_\text{CM}$ greater than 400 MeV/c. For each $K^- \pi^+ \pi^0$ combination, we use the kinematics of the decay products and the known properties of the Dalitz plot for this decay \cite{13} to compute the square of the decay amplitude $A^2$. We select combinations with $A^2$ greater than 5\% of its maximum value. This requirement selects mostly the $K^- \rho^+$ region of the Dalitz plot. It rejects 62\% of the combinatorial background, while keeping 76\% of the $D^0 \to K^- \pi^+ \pi^0$ signal, as measured with the $B^+ \to D^0 \pi^+$ sample. Combinations with invariant mass within $25 \text{ MeV}/c^2$ (2.5$\sigma$) of $m_{D^0}$ are retained.

The $D^0$ candidates are selected from combinations of a $D^0$ and a $\pi^0$ with $p_\pi^0 > 70 \text{ MeV}/c$. After kinematically constraining $D^0$ and $\pi^0$ candidates to their nominal masses, we select the candidates with a mass difference $\Delta m = |m(D^{(*)0}) - m(D^0)| - 142.2 \text{ MeV}/c^2| < 3.3 \text{ MeV}/c^2$ (3$\sigma$).

Two standard kinematic variables are used to select $B^0$ candidates: the energy-substituted mass $m_{ES} c^2 = \sqrt{(s + c^2 p_Y \cdot p_B)^2/E_Y - c^2 p_B^2}$ and the energy difference $\Delta E = E_B - \frac{1}{2} s$, where the asterisk denotes the CM frame, $s$ is the square of the total energy in the CM frame, $p$ and $E$ are, respectively, three-momentum and energy, and the subscripts $Y$ and $B$ refer to $Y(4S)$ and $B^0$. In calculating $p_B$ and $E_B$ we constrain the mass of the $D^{(*)0}$ and $K_S^0$ candidates to their respective nominal values. For signal events, $m_{ES}$ is centered around the $B^0$ mass with a resolution of about 2.6 $\text{ MeV}/c^2$, dominated by knowledge of the $e^+$ and $e^-$ beam energies. In simulated events the
ΔE resolution is found to be ≈ 13 MeV for all B⁰ decay modes considered in this analysis. The B⁰ candidates are required to have m_{ES} > 5.2 GeV/c² and |ΔE| < 100 MeV.

We use two variables to reject most of the remaining background, which is dominated by continuum events: a Fisher discriminant [14] based on the energy flow in the event and the polar angle θ_B of the B⁰ candidate in the CM frame. For correctly reconstructed B candidates cosθ_B follows a 1 – cos²(θ_B) distribution, whereas it is uniformly distributed for continuum events and combinatorial background. We require |cosθ_B| < 0.75 for B⁰ → D⁰K⁺⁰, and |cosθ_B| < 0.85 for all other decay modes. The Fisher discriminant F is defined as a linear combination of |cosθ_B| and two energy-flow moments L⁰ and L². The variable θ_B is the angle in the CM frame between the thrust axis [15] of the decay products of the B⁰ and the thrust axis of all charged and neutral particles in the event excluding the ones that form the B⁰. The energy-flow moments L⁰ and L² are defined as Lᵢ = ∑ᵢ pᵢ cos(θ_j) where pᵢ are the CM momentum and θ_j is the angle between the direction of particle j with respect to the thrust axis of the B⁰ candidate, and the sum is over all particles in the event (excluding those that form the B⁰). The requirement on F varies for each decay channel because of different levels of expected background. In the D⁺⁺Kangered and D⁺K⁻⁰ final states our requirement has an efficiency of about 80% for the signal while rejecting approximately 85% of the background; in the B⁰ → D⁰K⁺⁰ mode a tighter requirement rejects 95% of the background and has a signal efficiency of 55%.

In the D⁺⁺Kangered final state, approximately 5% of the events that satisfy all selection criteria contain more than one B⁰ candidate. We retain the candidate with the smallest χ² computed from the measured value of m(D⁺⁺) and m(D⁺⁺) = m(D⁰), their nominal values, and their resolutions in data. In the D⁺⁺Kangered and D⁺K⁻⁰ final states we retain all selected B⁰ candidates since the fraction of events with two or more candidates is negligible (< 1%).

The selected B⁰ → D(s)⁺K(s)⁻ candidates include small contributions from numbers of B decays to similar final states which are misreconstructed as signal candidates. We have studied these backgrounds with large samples of simulated events, corresponding to between 100 and 1000 times the size of our data sample, for the following categories of decays: (1) B⁰ → D⁰ρ⁺⁰, ρ⁺⁰ → π⁺π⁻, where one of the two pions is misidentified as a charged kaon; (2) B⁰ → D⁺π⁻ decays followed by Cabibbo-suppressed decays D⁺ → K⁺⁺K⁺, K⁺⁺π⁺, K⁺⁺π⁺, and B⁰ → D⁺K⁻ followed by D⁺ → K⁺⁺π⁺, K⁺⁺π⁻, and B⁰ → D⁺K⁻ followed by D⁺ → K⁺⁺π⁺, K⁺⁺π⁻, and D⁺ → K⁺⁻π⁺π⁻ reconstructed, respectively, in the D⁺(K⁺⁻π⁺K⁺⁺), D⁺(K⁺⁻π⁺π⁻)K⁺⁺, and D⁺(K⁺⁻π⁺π⁻)K⁺⁺ final states; (3) charmless B⁰ → K⁻π⁺K_S(ππ) where the K⁻ and π⁺ are wrongly combined to form a D⁰ → K⁻π⁺π⁺ candidate; (4) B⁰ → D⁺⁺K⁺⁺, D⁺⁺ → D⁺⁺γ candidates, where a low-energy photon is not reconstructed; (5) the decays B⁺ → D⁺⁺K⁺⁺, D⁺⁺ → D⁺⁺γ, B⁺ → D⁺⁺K⁺⁺, K⁺⁺ → K⁻π⁺π⁻, K⁺⁺ → K⁻π⁺π⁻, K⁺⁺ → D⁺⁺K⁺⁺, D⁺⁺ → D⁺⁺K⁺⁺, and B⁰ → D⁺⁺K⁺⁺, D⁺⁺ → D⁺⁺K⁺⁺, where a low-energy π⁺, π⁻, or photon is replaced by a random low-momentum charged particle. The contribution of category (1) is found to be less than 0.01 events and hence is neglected. The contribution of category (2) is also negligible in all modes, except for B → D⁺⁺Kangered, D⁺⁺ → K⁻π⁺π⁻. We eliminate 87% of these background events by requiring the invariant masses m(K⁺⁺K⁺) and m(K⁺⁺π⁺) to be more than 20 MeV/c² away from the nominal D⁺⁺ mass.

The signal yield for each B⁰ decay mode is determined with a two-dimensional extended unbinned maximum likelihood fit to the m_{ES} and ΔE distributions, separately for each D⁺⁺ decay mode. The probability density function (PDF) is a sum of three components: a signal component G(m_{ES}) × G(ΔE), a background component G(m_{ES}) × P_i(ΔE), accounting for other B decays misreconstructed as signal, and a combinatorial background component T(m_{ES}) × P_i(ΔE). Here, G(m_{ES}) is a Gaussian describing the m_{ES} distribution of signal and misreconstructed B decays; G(ΔE) is a Gaussian describing the signal ΔE distribution; P_i(ΔE) are first-order polynomials describing the ΔE distributions of background events. The m_{ES} distribution of the combinatorial background is parameterized by a threshold function T(m_{ES}) defined as T(m_{ES}) = m_{ES} / √[1 - x²] exp{−ξ(1 - x²)} [16], where x = 2m_{ES}/c²√/s and ξ is a shape parameter. The mean and the resolution of G(m_{ES}) and G(ΔE) are fixed to values measured in the B⁺ → D⁺⁺π⁺ calibration sample.

TABLE I. Signal yield N₅, signal significance S, effective signal efficiency εₑₛ, and the measured branching fraction B for the B⁺ → D⁺⁺Kangered, B⁺ → D⁺⁺Kangered, and B⁺ → D⁺⁺Kangered decays. The efficiency εₑₛ is defined as Σ_i ε_i × B_i, where the sum is over the D⁺⁺ decay modes, ε_i are the signal reconstruction efficiencies, and B_i are the corresponding intermediate branching fractions for D⁺⁺, D⁺⁺, Kangered, and Kangered to final states reconstructed in this analysis.

The measured signal yields are summarized in Table I. The $\Delta E$ distributions of candidates with $|m_{ES} - 5280| < 8 \text{ MeV}/c^2$ for the sums of the reconstructed $D^0$ decay modes are illustrated in Fig. 2. The signal significance $S$ is computed as $S = \sqrt{2(\ln L(N_S) - \ln L(N_S = 0))}$, where $L(N_S)$ is the likelihood of the nominal fit, and $L(N_S = 0)$ is the value obtained after repeating the fit with the signal yield $N_S$ constrained to be zero.

The branching fraction $B$ for each $B^0$ decay mode is the weighted average of the branching fractions $B_j$ in each $D^0$ channel $D_j = \{K^-\pi^+, K^-\pi^+\pi^+\pi^+, K^-\pi^+\pi^0\}$, computed as

$$B_j = \frac{N_j}{2 \times N_{BB} \times B(Y(4S) \rightarrow B\bar{B}B^0) \times B(D_j) \times B_K \times \epsilon_j},$$

where $N_j$ is the signal yield from the likelihood fit, $N_{BB}$ is the total number of $Y(4S) \rightarrow B\bar{B}$ events, $B_{D_j}$ is the branching fraction $B(D^0 \rightarrow D_j)$ in $B^0 \rightarrow D^0\bar{K}^{(*)0}$ and $B(D^0 \rightarrow D^0\pi^0) \times B(D^0 \rightarrow D_j)$ in $B^0 \rightarrow D^0\bar{K}^{(*)0}$, $B_K$ is the $K^0 \rightarrow \pi^+\pi^-(K^{(*)0} \rightarrow K^+\pi^-)$ branching fraction in $B^0 \rightarrow D^{(*)0}\bar{K}^{0}(B^0 \rightarrow D^0\bar{K}^{(*)0}, \bar{D}^0 \rightarrow K^-\pi^+\pi^-)$ decay modes, and $\epsilon_j$ is the signal reconstruction efficiency. The weights are calculated from the statistical and uncorrelated systematic uncertainties in $B_j$.

We assume $B(Y(4S) \rightarrow B\bar{B}B^0) = 0.5$. The systematic uncertainties for the branching fractions include contributions from estimated misreconstructed $B$ background (1–13%) [17], variation of parameters kept fixed in the likelihood fit (2–8%), $D^{(*)0}$ branching fraction (2.4–6.9%), $\pi^0$ reconstruction efficiency (3%), photon reconstruction efficiency (1.8%), charged-track reconstruction efficiency (0.8% per track), simulation statistics (1–4%), efficiency correction factors (1–4%), kaon identification efficiency (2% per kaon), $K_S^0$ reconstruction efficiency (1.6%), and the number of $B\bar{B}$ events (1.1%). The efficiency correction factors are obtained by comparing data with MC simulation in the $B^+ \rightarrow D^0\pi^+$ control sample. The largest contributions to the uncertainties in these factors are from selection requirements for the $\pi^0$ momentum $p_{\pi^0}$ and the amplitude $|A|$ in the $D^0 \rightarrow K^-\pi^+\pi^0$ decay and the Fisher discriminant $F$. We measure

\[
\begin{align*}
B(B^0 \rightarrow D^0\bar{K}^{(*)0}) &= (5.3 \pm 0.7 \pm 0.3) \times 10^{-5} \\
B(B^0 \rightarrow D^0\bar{K}^{(*)0}) &= (3.6 \pm 1.2 \pm 0.3) \times 10^{-5} \\
B(B^0 \rightarrow D^0\bar{K}^{(*)0}) &= (4.0 \pm 0.7 \pm 0.3) \times 10^{-5} \\
B(B^0 \rightarrow D^0\bar{K}^{(*)0}) &= (0.0 \pm 0.5 \pm 0.3) \times 10^{-5}
\end{align*}
\]

where the uncertainties are, respectively, statistical and systematic. For the decay $B^0 \rightarrow D^0\bar{K}^{(*)0}$ we use the Bayesian method to compute the upper limit $N_{UL}$ on the observed number of events. The value of $N_{UL}$ at 90% C.L. is defined as $\int_{0}^{N_{UL}} L(N) dN = 0.9$, where $L(N)$ is the likelihood function from the fit to the $m_{ES}$ and $\Delta E$ distributions. We assume a flat prior probability density function for $B > 0$. We account for systematic uncertainties by numerically convolving $L(N)$ with a Gaussian distribution with a width determined by the relative systematic uncertainty multiplied by the measured signal yield. We obtain $B(B^0 \rightarrow D^0\bar{K}^{(*)0}) < 1.1 \times 10^{-5}$ at 90% C.L.

We compute an upper limit on the ratio $\bar{r}_B$ by measuring the ratio $R_i$ in each $D^0$ decay mode. We use the expression $R_i = (e_{D_i,\bar{K}}/e_{D_i,\bar{K}}) \cdot (N_{D_i,\bar{K}}/N_{D_i,\bar{K}})$ to obtain the PDF for $R_i$ from the unbinned maximum likelihood fit described earlier. In this expression $e_{D_i,\bar{K}}$ and $N_{D_i,\bar{K}}$ ($N_{D_i,\bar{K}}$) are, respectively, the reconstruction efficiency and fitted yield of the $B^0 \rightarrow D^0\bar{K}^{(*)0}$, $D^0 \rightarrow K^-\pi^+\pi^0$ ($B^0 \rightarrow D^0\bar{K}^{(*)0}, D^0 \rightarrow K^-\pi^+\pi^0$) decay modes. The uncertainties on $e_{D_i,\bar{K}}$, $e_{D_i,\bar{K}}$, and $N_{D_i,\bar{K}}$ are used to obtain the posterior PDF $L(R_i)$ for each $R_i$. We assume a Gaussian PDF for $R_{D_i}$. We compute the PDF for $\bar{r}_B$ by convolving $L(R_i)$ and $R_{D_i}$ according to Eq. (1). We obtain the limit $\bar{r}_B < 0.40$ at 90% C.L. with a Bayesian method using uniform priors for $R_i > 0$ and by taking into account the full range $0^\circ - 180^\circ$ for $\gamma$ and $\delta_i$. The present signal yields combined with this limit on $\bar{r}_B$ suggest that a substantially larger data sample is needed for a competitive time-dependent measurement of $\sin(2\beta + \gamma)$ in $B^0 \rightarrow D^{(*)0}\bar{K}^{(*)0}$ decays.

In summary, we have presented measurements of the branching fractions for the decays $B^0 \rightarrow D^0\bar{K}^{(*)0}$ and $B^0 \rightarrow D^0\bar{K}^{(*)0}$, evidence for the decay $B^0 \rightarrow D^{(*)0}\bar{K}^{(*)0}$, and an upper limit for the ratio $\bar{r}_B$. Our results are in agreement with previous measurements of these modes [18].

We are grateful for the excellent luminosity and machine conditions provided by our PEP-II colleagues, and for the substantial dedicated effort from the computing organizations that support BABAR. The collaborating institutions
wish to thank SLAC for its support and kind hospitality. This work is supported by DOE and NSF (USA), NSERC (Canada), IHEP (China), CEA and CNRS-IN2P3 (France), BMBF and DFG (Germany), INFN (Italy), FOM (The Netherlands), NFR (Norway), MIST (Russia), and PPARC (United Kingdom). Individuals have received support from CONAcYT (Mexico), Marie Curie EIF (European Union), the A.P. Sloan Foundation, the Research Corporation, and the Alexander von Humboldt Foundation.
