(Received 17 July 2002; revised manuscript received 6 September 2002; published 29 October 2002)

We present results on time-dependent CP asymmetries in neutral B decays to several CP eigenstates. The measurements use a data sample of about 88×10^6 $Y(4S) \rightarrow B\bar{B}$ decays collected between 1999 and 2002 with the $BABAR$ detector at the PEP-II asymmetric-energy B factory at SLAC. We study events in which one neutral B meson is fully reconstructed in a final state containing a charmonium meson and the other B meson is determined to be either a B^0 or \bar{B}^0 from its decay products. The amplitude of the CP asymmetry, which in the standard model is proportional to $\sin 2\beta$, is derived from the decay-time distributions in such events. We measure $\sin 2\beta = 0.741 \pm 0.067(\text{stat}) \pm 0.034(\text{syst})$ and $|\lambda| = 0.948 \pm 0.051(\text{stat}) \pm 0.030(\text{syst})$. The magnitude of λ is consistent with unity, in agreement with the standard model expectation of no direct CP violation in these modes.

PACS numbers: 13.25.Hw, 11.30.Er, 12.15.Hh

The standard model of electroweak interactions describes CP violation in weak interactions as a consequence of a complex phase in the three-generation Cabibbo-Kobayashi-Maskawa (CKM) quark-mixing matrix [1]. In this framework, measurements of CP asym-

metries in the proper-time distribution of neutral B decays to charmonium final states provide a direct measurement of $\sin 2\beta$ [2], where $\beta \equiv \arg[-V_{cd}V_{cb}^*/V_{td}V_{tb}^*]$.

Observations of CP violation in B^0 decays were reported last year by the $BABAR$ [3] and Belle [4]

Collaborations. The PEP-II collider has since delivered an additional 63 fb^{-1} , thereby approximately tripling the data sample near the $Y(4S)$ resonance. In this Letter we report a more precise measurement of $\sin 2\beta$ using the full sample of about $88 \times 10^6 \overline{B}B$ decays. The *BABAR* detector and the measurement technique are described in detail in Refs. [5,6], respectively. Changes in the analysis with respect to the published result [3] include processing of all data with a uniform event reconstruction, a new flavor-tagging algorithm, and the addition of the decay mode $B^0 \rightarrow \eta_c K_S^0$.

We reconstruct a sample of neutral B mesons (B_{CP}) decaying to the final states $J/\psi K_S^0$, $\psi(2S)K_S^0$, $\chi_{c1}K_S^0$, $\eta_c K_S^0$, $J/\psi K^{*0}$ ($K^{*0} \rightarrow K_S^0 \pi^0$), and $J/\psi K_L^0$. The J/ψ and $\psi(2S)$ mesons are reconstructed through their decays to e^+e^- and $\mu^+\mu^-$; the $\psi(2S)$ is also reconstructed through its decay to $J/\psi \pi^+ \pi^-$. We reconstruct χ_{c1} mesons in the decay mode $J/\psi \gamma$ and η_c mesons in the $K_S^0 K^+ \pi^-$ and $K^+ K^- \pi^0$ final states [7]. The K_S^0 is reconstructed in its decay to $\pi^+ \pi^-$ (and to $\pi^0 \pi^0$ for the $J/\psi K_S^0$ mode). We examine each event in the B_{CP} sample for evidence that the recoiling B meson decayed as a B^0 or \overline{B}^0 (flavor tag).

The proper-time distribution of B meson decays to a CP eigenstate with a B^0 or \overline{B}^0 tag can be expressed in terms of a complex parameter λ that depends on both the B^0 - \overline{B}^0 oscillation amplitude and the amplitudes describing \overline{B}^0 and B^0 decays to this final state [8]. The decay rate $f_{\pm}(f_{\pm})$ when the tagging meson is a B^0 (\overline{B}^0) is given by

$$f_{\pm}(\Delta t) = \frac{e^{-|\Delta t|/\tau_{B^0}}}{4\tau_{B^0}} \left[1 \pm \frac{2\text{Im}\lambda}{1+|\lambda|^2} \sin(\Delta m_d \Delta t) \mp \frac{1-|\lambda|^2}{1+|\lambda|^2} \cos(\Delta m_d \Delta t) \right], \quad (1)$$

where $\Delta t = t_{\text{rec}} - t_{\text{tag}}$ is the difference between the proper decay times of the reconstructed B meson (B_{rec}) and the tagging B meson (B_{tag}), τ_{B^0} is the B^0 lifetime, and Δm_d is the B^0 - \overline{B}^0 oscillation frequency. The sine term in Eq. (1) is due to the interference between direct decay and decay after flavor change, and the cosine term is due to the interference between two or more decay amplitudes with different weak and strong phases. CP violation can be observed as a difference between the Δt distributions of B^0 - and \overline{B}^0 -tagged events or as an asymmetry with respect to $\Delta t = 0$ for either flavor tag.

In the standard model, $\lambda = \eta_f e^{-2i\beta}$ for charmonium-containing $b \rightarrow c\bar{c}s$ decays, where η_f is the CP eigenvalue of the final state f . Thus, the time-dependent CP asymmetry is

$$A_{CP}(\Delta t) \equiv \frac{f_{+}(\Delta t) - f_{-}(\Delta t)}{f_{+}(\Delta t) + f_{-}(\Delta t)} = -\eta_f \sin 2\beta \sin(\Delta m_d \Delta t), \quad (2)$$

with $\eta_f = -1$ for $J/\psi K_S^0$, $\psi(2S)K_S^0$, $\chi_{c1}K_S^0$, and $\eta_c K_S^0$, and $+1$ for $J/\psi K_L^0$. Because of the presence of even ($L =$

$0, 2$) and odd ($L = 1$) orbital angular momenta in the $B \rightarrow J/\psi K^{*0}$ final state, there can be CP -even and CP -odd contributions to the decay rate. When the angular information in the decay is ignored, the measured CP asymmetry in $J/\psi K^{*0}$ is reduced by a factor $1 - 2R_{\perp}$, where R_{\perp} is the fraction of the $L = 1$ component. We have measured $R_{\perp} = (16.0 \pm 3.5)\%$ [9], which gives $\eta_f = 0.65 \pm 0.07$ after acceptance corrections in the $J/\psi K^{*0}$ mode.

The event selection, lepton, and K^{\pm} identification, and J/ψ and $\psi(2S)$ reconstruction used in this analysis are similar to those described in Ref. [6], as are the selection criteria for the channels $J/\psi K_S^0$, $\psi(2S)K_S^0$, $\chi_{c1}K_S^0$, $J/\psi K^{*0}$, and $J/\psi K_L^0$. The $B^0 \rightarrow \eta_c K_S^0$ sample selection is described in Ref. [10]. In brief, the K^{\pm} candidates must satisfy kaon identification criteria and the $K_S^0 \rightarrow \pi^+ \pi^-$ and $\pi^0 \rightarrow \gamma\gamma$ candidates are required to have reconstructed masses within 12.5 and 15 MeV/c^2 , respectively, of their nominal masses [11]. The η_c candidates (with $2.90 < M_{KK\pi} < 3.15 \text{ GeV}/c^2$) are combined with $K_S^0 \rightarrow \pi^+ \pi^-$ candidates reconstructed within 10 MeV/c^2 of the K_S^0 nominal mass to form a B^0 candidate. This sample includes a contribution of $(15 \pm 2)\%$ from hadronic J/ψ decays to the $KK\pi$ final states.

We select candidates in the $B^0 \rightarrow J/\psi K_S^0$, $\psi(2S)K_S^0$, $\chi_{c1}K_S^0$, and $J/\psi K^{*0}$ samples by requiring that the difference ΔE between their energy and the beam energy in the center-of-mass frame be less than 3 standard deviations from zero. The ΔE resolution is about 10 MeV , except for the mode with $K_S^0 \rightarrow \pi^0 \pi^0$ (33 MeV) and with K^{*0} (20 MeV). The $B^0 \rightarrow \eta_c K_S^0$ candidates are required to have $|\Delta E|$ less than 40 (70) MeV for the $K_S^0 K^+ \pi^-$ ($K^+ K^- \pi^0$) modes. For all modes except $J/\psi K_L^0$, the beam-energy substituted mass $m_{\text{ES}} = \sqrt{(E_{\text{beam}}^{\text{c.m.}})^2 - (p_B^{\text{c.m.}})^2}$ must be greater than 5.2 GeV/c^2 . To determine numbers of events and purities, a signal region $5.270(5.273) < m_{\text{ES}} < 5.290(5.288) \text{ GeV}/c^2$ is used for modes containing K_S^0 (K^{*0}). In the $J/\psi K_L^0$ mode, the ΔE resolution is 3.5 MeV (after B mass constraint) and the signal region is defined by $|\Delta E| < 10 \text{ MeV}$.

A measurement of A_{CP} requires a determination of the experimental Δt resolution and the fraction w of events in which the tag assignment is incorrect. This mistag fraction reduces the observed CP asymmetry by a factor $1 - 2w$. Mistag fractions and Δt resolution functions are determined from a sample of neutral B mesons that decay to flavor eigenstates (B_{flav}) consisting of the channels $D^{(*)-} h^+$ ($h^+ = \pi^+, \rho^+$, and a_1^+) and $J/\psi K^{*0}$ ($K^{*0} \rightarrow K^+ \pi^-$). Validation studies are performed with a control sample of B^+ mesons decaying to the final states $J/\psi K^{(*)+}$, $\psi(2S)K^+$, $\chi_{c1}K^+$, $\eta_c K^+$, and $\overline{D}^{(*)0} \pi^+$.

We use multivariate algorithms to identify signatures of B decays that determine the flavor of B_{tag} . Primary leptons from semileptonic B decays are selected from identified electrons and muons as well as isolated

energetic tracks. We use the charges of identified kaon candidates to define a kaon tag. Soft pions from D^{*+} decays are selected on the basis of their momentum and direction with respect to the thrust axis of B_{tag} . A neural network, which combines the outputs of these physics-based algorithms, takes into account correlations between different sources of flavor information and provides an estimate of the mistag probability for each event.

By using the outputs of the physics-based algorithms and the estimated mistag probability, each event is assigned to one of four hierarchical, mutually exclusive tagging categories. The Lepton category contains events with an identified lepton and a supporting kaon tag if present. Events with a kaon candidate and soft pion with opposite charge and similar flight direction are assigned to the Kaon I category. Events with only a kaon tag are assigned to the Kaon I or the Kaon II category depending on the estimated mistag probability. The Kaon II category also contains the remaining events with a soft pion. All other events are assigned to the Inclusive category or excluded from further analysis based on the estimated mistag probability. The tagging efficiencies ϵ_i for the four tagging categories are measured from data and summarized in Table I. The figure of merit for tagging is the effective tagging efficiency $Q \equiv \sum_i \epsilon_i (1 - 2w_i)^2$. This algorithm improves Q by about 7% (relative) over the algorithm used in Ref. [6].

The time interval Δt between the two B decays is calculated from the measured separation Δz between the decay vertices of B_{rec} and B_{tag} along the collision (z) axis [6]. We determine the z position of the B_{rec} vertex from its charged tracks. The B_{tag} decay vertex is determined by fitting tracks not belonging to the B_{rec} candidate to a common vertex, employing constraints from the beam spot location and the B_{rec} momentum [6]. We accept events with a Δt uncertainty of less than 2.5 ps and $|\Delta t| < 20$ ps. The fraction of events satisfying these requirements is 95%. The rms Δt resolution for 99.7% of these events is 1.1 ps.

The signal region contains 2641 events which satisfy the tagging and vertexing requirements. In Table II we list the number of events and the signal purity for the tagged B_{CP} candidates. The purities are determined from fits to the m_{ES} (all K_S^0 modes) or ΔE (K_L^0 mode) distributions in

TABLE I. Efficiencies ϵ_i , average mistag fractions w_i , mistag fraction differences $\Delta w_i = w_i(B^0) - w_i(\bar{B}^0)$, and Q extracted for each tagging category i from the B_{flav} and B_{CP} samples.

Category	ϵ (%)	w (%)	Δw (%)	Q (%)
Lepton	9.1 ± 0.2	3.3 ± 0.6	-1.5 ± 1.1	7.9 ± 0.3
Kaon I	16.7 ± 0.2	10.0 ± 0.7	-1.3 ± 1.1	10.7 ± 0.4

Inclusive	20.0 ± 0.3	31.5 ± 0.9	-2.4 ± 1.3	2.7 ± 0.3
All	65.6 ± 0.5			28.1 ± 0.7

data or from Monte Carlo simulation (K^{*0} mode). Figure 1 shows the m_{ES} distribution for modes containing a K_S^0 or K^{*0} and the ΔE distribution for the $J/\psi K_L^0$ candidates. For all modes except $\eta_c K_S^0$ and $J/\psi K_L^0$, we use simulated events to estimate the fractions of events in the Gaussian component of the m_{ES} fits due to cross feed from other decay modes. For the $\eta_c K_S^0$ mode the cross-feed fraction is determined from a fit to the $M_{KK\pi}$ and m_{ES} distributions. These fractions range from $(0.3 \pm 0.1)\%$ for $J/\psi K_S^0$ ($K_S^0 \rightarrow \pi^+ \pi^-$) to $(13.1 \pm 5.9)\%$ for $\eta_c K_S^0$. For the $J/\psi K_L^0$ and $J/\psi K^{*0}$ decay modes, the composition, effective η_f , and ΔE distribution ($J/\psi K_L^0$ only) of the individual background sources are determined either from simulation (for $B \rightarrow J/\psi X$) or from the $m_{\ell^+ \ell^-}$ sidebands in data (for fake $J/\psi \rightarrow \ell^+ \ell^-$).

We determine $\sin 2\beta$ with a simultaneous unbinned maximum likelihood fit to the Δt distributions of the tagged B_{CP} and B_{flav} samples. In this fit the Δt distributions of the B_{CP} sample are described by Eq. (1) with $|\lambda| = 1$. The Δt distributions of the B_{flav} sample evolve according to the known frequency for flavor oscillation in B^0 mesons. The observed amplitudes for the CP asymmetry in the B_{CP} sample and for flavor oscillation in the B_{flav} sample are reduced by the same factor $1 - 2w$ due to flavor mistags. Events are assigned signal and background probabilities based on the m_{ES} (all modes except $J/\psi K^{*0}$ and $J/\psi K_L^0$) or ΔE ($J/\psi K_L^0$) distributions. The Δt distributions for the signal are convolved with a common resolution function, modeled by the sum of three Gaussians [6]. Backgrounds are incorporated with an empirical description of their Δt spectrum, containing prompt and nonprompt components convolved with a resolution function [6] distinct from that of the signal.

FIG. 1. Distributions for B_{CP} candidates satisfying the tagging and vertexing requirements: (a) m_{ES} for the final states $J/\psi K_S^0$, $\psi(2S) K_S^0$, $\chi_{c1} K_S^0$, $\eta_c K_S^0$, and $J/\psi K^{*0}$ ($K^{*0} \rightarrow K_S^0 \pi^0$), and (b) ΔE for the final state $J/\psi K_L^0$.

TABLE II. Number of events N_{tag} in the signal region after tagging and vertexing requirements, signal purity P , and results of fitting for CP asymmetries in the B_{CP} sample and in various subsamples, as well as in the B_{flav} and charged B control samples. Errors are statistical only.

Sample	N_{tag}	$P(\%)$	$\sin 2\beta$
$J/\psi K_S^0, \psi(2S)K_S^0, \chi_{c1}K_S^0, \eta_c K_S^0$	1506	94	0.76 ± 0.07
$J/\psi K_L^0$ ($\eta_f = +1$)	988	55	0.72 ± 0.16

There are 34 free parameters in the fit: $\sin 2\beta$ (1), the average mistag fractions w and the differences Δw between B^0 and \bar{B}^0 mistag fractions for each tagging category (8), parameters for the signal Δt resolution (8), and parameters for background time dependence (6), Δt resolution (3), and mistag fractions (8). We fix $\tau_{B^0} = 1.542$ ps and $\Delta m_d = 0.489$ ps $^{-1}$ [11]. The determination of the mistag fractions and Δt resolution function parameters for the signal is dominated by the high-statistics B_{flav} sample. The measured mistag fractions are listed in Table I. Background parameters are determined from events with $m_{\text{ES}} < 5.27$ GeV/ c^2 (except $J/\psi K_L^0$ and $J/\psi K^{*0}$). The largest correlation between $\sin 2\beta$ and any linear combination of the other free parameters is 0.13. We observe a bias of 0.014 ± 0.005 in the fitted value of $\sin 2\beta$ in simulated events. Part of this bias (0.004) is due to a correlation between the mistag fractions and the Δt resolution not explicitly incorporated in the fit. Therefore we subtract 0.014 from the fitted value of $\sin 2\beta$ in data and include 0.010 in the systematic error.

The fit to the B_{CP} and B_{flav} samples yields

$$\sin 2\beta = 0.741 \pm 0.067(\text{stat}) \pm 0.034(\text{syst}).$$

Figure 2 shows the Δt distributions and asymmetries in yields between B^0 tags and \bar{B}^0 tags for the $\eta_f = -1$ and

$\eta_f = +1$ samples as a function of Δt , overlaid with the projection of the likelihood fit result.

The dominant sources of systematic error are the uncertainties in the level, composition, and CP asymmetry of the background in the selected CP events (0.023), the assumed parametrization of the Δt resolution function (0.017), due in part to residual uncertainties in the internal alignment of the vertex detector, and possible differences between the B_{flav} and B_{CP} mistag fractions (0.012). The total systematic error is 0.034. Most systematic errors are determined with data and will continue to decrease with additional statistics.

The large B_{CP} sample allows a number of consistency checks, including separation of the data by decay mode, tagging category, and B_{tag} flavor. The results of fits to these $\eta_f = -1$ subsamples are shown in Table II and found to be statistically consistent. The results of fits to the control samples of non- CP decay modes indicate no statistically significant asymmetry.

We also measure the parameter $|\lambda|$ in Eq. (1) from a fit to the $\eta_f = -1$ sample, which has high purity and requires minimal assumptions on the effect of backgrounds. This parameter is sensitive to the difference in the number of B^0 - and \bar{B}^0 -tagged events. In order to account for differences in reconstruction and tagging efficiencies for B^0 and \bar{B}^0 mesons, we incorporate five

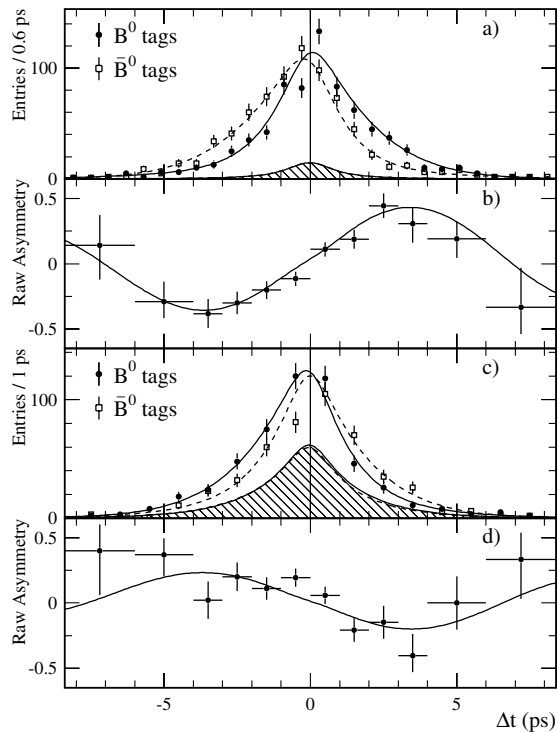

FIG. 2. (a) Number of $\eta_f = -1$ candidates ($J/\psi K_S^0$, $\psi(2S)K_S^0$, $\chi_{c1}K_S^0$, and $\eta_c K_S^0$) in the signal region with a B^0 tag N_{B^0} and with a \bar{B}^0 tag $N_{\bar{B}^0}$, and (b) the raw asymmetry $(N_{B^0} - N_{\bar{B}^0})/(N_{B^0} + N_{\bar{B}^0})$ as functions of Δt . The solid (dashed) curves represent the fit projection in Δt for B^0 (\bar{B}^0) tags. The shaded regions represent the background contributions. (c) and (d) contain the corresponding information for the $\eta_f = +1$ mode $J/\psi K_L^0$.

additional free parameters in this fit. We obtain $|\lambda| = 0.948 \pm 0.051(\text{stat}) \pm 0.030(\text{syst})$. The coefficient of the $\sin(\Delta m_d \Delta t)$ term in Eq. (1) is measured to be $0.759 \pm 0.074(\text{stat})$. The dominant contribution to the systematic error for $|\lambda|$, conservatively estimated to be 0.025, is due to interference between the suppressed $\bar{b} \rightarrow \bar{u}cd$ amplitude with the favored $b \rightarrow c\bar{u}d$ amplitude for some tag-side B decays. The other sources of systematic error for $|\lambda|$ are the same as in the $\sin 2\beta$ measurement.

This measurement of $\sin 2\beta$ supersedes our previous result [3] and improves upon the precision of each of the previous measurements [3,4] by a factor of 2. While the measured value is consistent with the range implied by

the measurements and theoretical estimates of the magnitudes of CKM matrix elements in the context of the standard model, it provides a precise and model-independent constraint on the position of the apex of the Unitarity Triangle [12].

We are grateful for the excellent luminosity and machine conditions provided by our PEP-II colleagues, and for the substantial dedicated effort from the computing organizations that support *BABAR*. The collaborating institutions wish to thank SLAC for its support and kind hospitality. This work is supported by DOE and NSF (U.S.A.), NSERC (Canada), IHEP (China), CEA and CNRS-IN2P3 (France), BMBF and DFG (Germany), INFN (Italy), NFR (Norway), MIST (Russia), and PPARC (United Kingdom). Individuals have received support from the A. P. Sloan Foundation, Research Corporation, and Alexander von Humboldt Foundation.
