AN ELEMENTARY DEFINABILITY THEOREM FOR FIRST ORDER LOGIC

C. BUTZ AND I. MOERDIJK

In this paper, we will present a definability theorem for first order logic. This theorem is very easy to state, and its proof only uses elementary tools. To explain the theorem, let us first observe that if \( M \) is a model of a theory \( T \) in a language \( \mathcal{L} \), then, clearly, any definable subset \( S \subseteq M \) (i.e., a subset \( S = \{ a \mid M \models \varphi(a) \} \) defined by some formula \( \varphi \)) is invariant under all automorphisms of \( M \). The same is of course true for subsets of \( M^n \) defined by formulas with \( n \) free variables.

Our theorem states that, if one allows Boolean valued models, the converse holds. More precisely, for any theory \( T \) we will construct a Boolean valued model \( M \), in which precisely the \( T \)-provable formulas hold, and in which every (Boolean valued) subset which is invariant under all automorphisms of \( M \) is definable by a formula of \( \mathcal{L} \).

Our presentation is entirely self-contained, and only requires familiarity with the most elementary properties of model theory. In particular, we have added a first section in which we review the basic definitions concerning Boolean valued models.

The Boolean algebra used in the construction of the model will be presented concretely as the algebra of closed and open subsets of a topological space \( X \) naturally associated with the theory \( T \). In an appendix, we will explain how the construction of this space is related to the construction of a similar space in [3]. In fact, one of the results in that paper could be interpreted as a definability theorem for infinitary logic, using topological rather than Boolean valued models.

There are various known definability theorems which are somewhat similar in form to our result but do not use Boolean valued models. The results are often inspired by Beth's theorem [1]. Some of these [10, 7] concern definability in infinitary languages. Svenonius' theorem [11] is for finitary logic, but concerns complete theories and uses 'big' models. (Cf. also Corollary 10.5.2 in [5].) Thus, our construction shows that the use of (small) Boolean valued models instead of big models allows for an explicit and elementary proof of a similar definability theorem.

§1. Preliminary definitions. In this section we review the basic definitions concerning Boolean valued models (see, e.g., [6]). Most readers will be familiar with these notions, and they are advised to skip this section. They should note, however,
that our Boolean algebras are not necessarily complete, and that we treat constants
and function symbols as functional relations.

Let us fix a signature $S$, consisting of constants, function and relation symbols.
For simplicity we assume it is a single sorted signature, although this restriction is
by no means essential. Let $\mathcal{L}$ denote the associated first order language $\mathcal{L}_{\omega_0}(S)$.

A Boolean valued interpretation of $\mathcal{L}$ is a triple $\mathcal{M} = (B, \mathcal{M}, [-])$, where $B$ is
a Boolean algebra, $|\mathcal{M}|$ is the underlying set of the interpretation, and $[-]$ is an
operation which assigns to each formula $\varphi(x_1, \ldots, x_n)$ of $\mathcal{L}$ with free variables
among $x_1, \ldots, x_n$ a function $|\mathcal{M}|^n \to B$, whose value at $(m_1, \ldots, m_n)$ is denoted

$$\llbracket \varphi(m_1, \ldots, m_n) \rrbracket.$$

These functions are required to satisfy the usual identities (where we write $m$ for $m_1, \ldots, m_n$):

(i) $\llbracket \varphi \land \psi(m) \rrbracket = \llbracket \varphi(m) \rrbracket \land \llbracket \psi(m) \rrbracket$ and similar for the other Boolean connectives.

(ii) $\llbracket \exists y \varphi(y, m) \rrbracket = \lor \{ \llbracket \varphi(k, m) \rrbracket \mid k \in |\mathcal{M}| \}$,

$\llbracket \forall y \varphi(y, m) \rrbracket = \land \{ \llbracket \varphi(k, m) \rrbracket \mid k \in |\mathcal{M}| \}$,

where it is part of the definition of an interpretation that these sups and infs are
required to exist in $B$. Finally, we require

(iii) if $\vdash \varphi(x_1, \ldots, x_n)$ then $\llbracket \varphi(m) \rrbracket = 1_B$ for any $m \in |\mathcal{M}|^n$.

In (iii), $\vdash$ denotes derivability in (one of the usual axiomatisations of) classical first
order logic.

**Remark 1.1.**

(i) Observe that, in particular, $|\mathcal{M}|$ is equipped with a $B$-valued equality

$$\llbracket x_1 = x_2 \rrbracket: |\mathcal{M}|^2 \to B,$

satisfying the identities for reflexivity, transitivity and symmetry,

$$\llbracket m = m \rrbracket = 1_B,$n

$$\llbracket m_1 = m_2 \rrbracket = \llbracket m_2 = m_1 \rrbracket,$n

$$\llbracket m_1 = m_2 \rrbracket \land \llbracket m_2 = m_3 \rrbracket \leq \llbracket m_1 = m_3 \rrbracket.$n

(ii) For each constant $c$ the formulas $c = x$ and $x = c$ define the same function

$C = \llbracket c = x \rrbracket: |\mathcal{M}| \to B$, which should be viewed as the interpretation of $c$. It

satisfies the conditions

$$C(m) \land \llbracket m = m' \rrbracket \leq C(m') \quad \text{and} \quad \lor \{ C(m) \mid m \in |\mathcal{M}| \} = 1_B.$n

Similarly, each $n$-ary function symbol is interpreted, via the formula

$$f(x_1, \ldots, x_n) = y,$n

by a function $F: |\mathcal{M}|^n \times |\mathcal{M}| \to B$. This function satisfies the conditions

$$F(m, k) \land \llbracket m = m' \rrbracket \land \llbracket k = k' \rrbracket \leq F(m', k')$$

and

$$\lor \{ F(m, k) \mid k \in |\mathcal{M}| \} = 1_B.$n

(Here $m = m_1, \ldots, m_n$ as before, and $[m = m']$ stands for $\land_{i=1}^n [m_i = m'_i]$.)
(iii) For each $n$-ary relation symbol $r$ the formula $r(x_1, \ldots, x_n)$ defines a map $R: |\mathcal{M}|^n \to B$, which is extensional in the sense that

$$R(m) \land [m = m'] \leq R(m').$$

(iv) The entire interpretation is determined by these data in (i)–(iii). First, using derivability of usual equivalences such as

$$\vdash f(g(x)) = y \leftrightarrow \exists z(f(z) = y \land g(x) = z),$$

one obtains by induction for each term $t(x_1, \ldots, x_n)$ a function $T: |\mathcal{M}|^{n+1} \to B$ interpreting the formula $t(x_1, \ldots, x_n) = y$. Next, one builds up the interpretation of formulas in the standard way, using the assumption that all necessary sups and infs exist in $B$.

As usual, we write $\mathcal{M} \models \varphi$ if $[\varphi(m)] = 1$ for all $m \in |\mathcal{M}|^n$, and we say $\mathcal{M}$ is a model of a theory $T$ if $\mathcal{M} \models \varphi$ whenever $T \vdash \varphi$. In this case, we write $\mathcal{M} \models T$, as usual.

§2. Automorphisms of models and statement of the theorem. Consider a fixed Boolean valued model $\mathcal{M} = (B, |\mathcal{M}|, [-])$. An automorphism $\pi$ of $\mathcal{M}$ consists of two mappings $\pi_0$ and $\pi_1$. The map $\pi_0: B \to B$ is an automorphism of the Boolean algebra $B$, while $\pi_1: |\mathcal{M}| \to |\mathcal{M}|$ is an automorphism of the underlying set $|\mathcal{M}|$, with the property that

$$\pi_0([\varphi(m_1, \ldots, m_n)]) = [\varphi(\pi_1(m_1), \ldots, \pi_1(m_n))],$$

for any formula $\varphi(x_1, \ldots, x_n)$ and any $m_1, \ldots, m_n \in |\mathcal{M}|$. (Of course it is enough to check a condition like (1) for constants, functions and relations of $\mathcal{S}$, and deduce (1) for arbitrary $\varphi$ by induction.)

An ($n$-ary) predicate on $\mathcal{M}$ is a map $p: |\mathcal{M}|^n \to B$ which satisfies the extensionality condition

$$p(m) \land [m = m'] \leq p(m')$$

for any $m, m' \in |\mathcal{M}|^n$ (where $[m = m']$ stands for $\bigwedge_{i=1}^n [m_i = m'_i]$, as before). Such a predicate $p$ is definable if there is a formula $\varphi(x_1, \ldots, x_n)$ such that

$$p(m) = [\varphi(m)],$$

for all $m \in |\mathcal{M}|^n$.

It is invariant under an automorphism $\pi$ if

$$\pi_0 p(m) = p(\pi_1(m)),$$

for all $m \in |\mathcal{M}|^n$,

(where $\pi_1(m)$ is $(\pi_1(m_1), \ldots, \pi_1(m_n))$). Obviously, every definable predicate is invariant. Our theorem states the converse.

Theorem 2.1. Let $T$ be any first order theory. There exists a Boolean valued model $\mathcal{M}$ such that

(i) $\mathcal{M}$ is a conservative model of $T$, in the sense that $\mathcal{M} \models \varphi$ if and only if $T \vdash \varphi$, for any sentence $\varphi$.

(ii) Any predicate which is invariant under all automorphisms of $\mathcal{M}$ is definable.

Before proving the theorem in §4, we will first give an explicit description of the Boolean algebra and the interpretation involved in the next section.
§3. Construction of the model. Our Boolean algebra will be defined as the algebra of all clopen (i.e., closed and open) sets in a topological space $X$. To describe $X$, let $\kappa \geq \omega$ be the cardinality of our language $\mathcal{L}$. We fix a set $\mathcal{S}_T$ of (ordinary, two-valued) models $M$ of $T$ such that every model of cardinality $\leq \kappa$ is isomorphic to a model in $\mathcal{S}_T$. Then, in particular, a formula is provable from $T$ if and only if it holds in all models in the set $\mathcal{S}_T$.

**Definition 3.1.** An enumeration of a model $M$ is a function $\alpha : \kappa \to |M|$ such that $\alpha^{-1}(a)$ is infinite for all $a \in |M|$ (here $|M|$ is the underlying set of $M$).

The space $X$ has as its points the equivalence classes of pairs $(M, \alpha)$, where $M \in \mathcal{S}_T$ and $\alpha$ is an enumeration of $M$. Two such pairs $(M, \alpha)$ and $(N, \beta)$ are equivalent if there exists an isomorphism of models $\theta : M \cong N$ such that $\beta = \theta \circ \alpha$. We will often simply write $(M, \alpha)$ when we mean the equivalence class of $(M, \alpha)$. The topology of $X$ is generated by all the basic open sets of the form

$$U_{\varphi, \xi} = \{ (M, \alpha) \mid M \models \varphi(\alpha(\xi)) \}.$$  

Here $\varphi = \varphi(x_1, \ldots, x_n)$ is any formula with free variables among $x_1, \ldots, x_n$, while $\xi = (\xi_1, \ldots, \xi_n)$ is a sequence of elements of $\kappa$ (i.e., ordinals $\xi_i < \kappa$); we use $\alpha(\xi)$ as an abbreviation of $\alpha(\xi_1), \ldots, \alpha(\xi_n)$.

Observe that each such basic open set $U_{\varphi, \xi}$ is also closed, with complement $U_{-\varphi, \xi}$. So $X$ is a zero-dimensional space. We now define the Boolean algebra $B$ as

$$B = \text{Clopen}(X),$$

the algebra of all open and closed sets in $X$.

Notice that arbitrary suprema need not exist in $B$, although $B$ has many infinite suprema. In particular, if $U \subset X$ is clopen and $\{U_i\}_{i \in I}$ is a cover of $U$ by basic open sets, then the union $\bigcup_{i \in I} U_i$ defines a supremum $U = \bigvee_{i \in I} U_i$ in $B$; we only need suprema of this kind.

The Boolean algebra $B$ just constructed is part of a natural Boolean valued model $\mathbb{M} = (B, |\mathbb{M}|, \llbracket \cdot \rrbracket)$, with

$$|\mathbb{M}| = \kappa$$

and evaluation of formulas defined by

$$\llbracket \varphi(\xi_1, \ldots, \xi_n) \rrbracket = U_{\varphi, \xi},$$

for any formula $\varphi(x_1, \ldots, x_n)$ and any sequence $\xi = (\xi_1, \ldots, \xi_n)$ of ordinals $\xi_i < \kappa$.

**Lemma 3.2.** This evaluation defines a $B$-valued interpretation of the language $\mathcal{L}$.

**Proof.** One needs to check the requirements (i)–(iii) from Section 1. Now (iii) is clear, while (i) and (ii) are completely straightforward. For illustration, we give the case of the existential quantifier. Suppose $\varphi(y, x)$ is a formula with just two free
variables $x$ and $y$. Then for any $\xi < \kappa$,
\[
[\exists y \varphi(y, \xi)] = \{ (M, \alpha) \mid M \models \exists y \varphi(y, \alpha(\xi)) \}
= \{ (M, \alpha) \mid \exists \eta < \kappa : M \models \varphi(\alpha(\eta), \alpha(\xi)) \}
\text{(since each } \alpha \text{ is surjective)}
= \bigcup_{\eta < \kappa} \{ (M, \alpha) \mid M \models \varphi(\alpha(\eta), \alpha(\xi)) \}
= \bigcup_{\eta < \kappa} [\varphi(\eta, \xi)],
\]
and this union is a supremum in $B$, by the remark above. 

$\S 4$. Proof of the theorem. We will now show that the interpretation $\mathcal{M}$ has the two properties stated in Theorem 2.1. The first one is easy:

**Proposition 4.1.** $\mathcal{M}$ is a conservative model of $T$.

**Proof.** We need to show that $\mathcal{M} \models \sigma$ if and only if $T \vdash \sigma$, for any sentence $\sigma \in \mathcal{L}$. By Lemma 3.2,
\[
[\sigma] = \{ (M, \alpha) \mid M \models \sigma \}.
\]
Thus $[\sigma] = X$ if and only if $M \models \sigma$ for all $M \in \mathcal{M}$, and this holds if and only if $T \vdash \sigma$, by definition of $\mathcal{M}$.

For the proof of the definability result 2.1(ii), we shall only need a particular collection of automorphisms of the model $\mathcal{M}$. Let $S_\kappa$ denote the symmetric group of permutations of $\kappa$. Then $S_\kappa$ acts on the model $\mathcal{M}$ as follows. Any $\pi \in S_\kappa$ induces a homeomorphism $\pi_\mathcal{M}: X \to X$, defined by
\[
\pi_\mathcal{M}(M, \alpha) = (M, \alpha \circ \pi^{-1}).
\]
This map has the property that $\pi_\mathcal{M}(U_{\varphi, \xi}) = U_{\varphi, \pi(\xi)}$, or
\[
\pi_\mathcal{M}[\varphi(\xi)] = [\varphi(\pi(\xi))],
\]
for any formula $\varphi(x_1, \ldots, x_n)$ and any $\xi = \xi_1, \ldots, \xi_n < \kappa$. Thus, the pair $\pi = (\pi_1, \pi_0)$ is an automorphism of $\mathcal{M}$. This defines an action of $S_\kappa$ on $\mathcal{M}$, i.e., a representation
\[
\rho: S_\kappa \to \text{Aut}(\mathcal{M}), \quad \rho(\pi_1) = \pi.
\]
For the second part of Theorem 2.1, it will now be enough to show:

**Proposition 4.2.** Any $S_\kappa$-invariant predicate is definable.

To simplify notation, we will only prove this for a unary predicate. So let us fix such an invariant predicate $p$. It is a function $p: |\mathcal{M}| = \kappa \to B$ satisfying the extensionality condition
\[
p(\xi) \land [\xi = \xi'] \leq p(\xi'),
\]
as well as the invariance condition
\[
p(\pi(\xi)) = \pi_0(p(\xi)),
\]
for any $\pi_1 \in S_\kappa$. We will first show that $p$ is "locally" definable (Lemma 4.5).
Lemma 4.3. Let \((M, \alpha) \in U \subseteq B\) and \(\eta_0 \in \kappa\). Then there is a formula \(\delta(x_1, \ldots, x_n, y)\) and elements \(\xi_1, \ldots, \xi_n \in \kappa\) such that

(i) \((M, \alpha) \in U_{\delta, (\xi, \eta_0)} \subseteq U\).
(ii) For any point \((N, \beta)\) in \(X\), any \(b_1, \ldots, b_n, c \in |N|\) such that

\[
N \models \delta(b_1, \ldots, b_n, c),
\]

and any \(\eta \in \kappa\) with \(\beta(\eta) = c\), there exists \(\pi_1 \in S_\kappa\) such that \(\pi_1(\eta) = \eta_0\) and \(\pi_0(N, \beta) \in U_{\delta, (\xi, \eta_0)}\).

Proof. Choose a basic open set \(U_{\delta', \xi} \subseteq B\), given by a formula \(\delta'(x_1, \ldots, x_n)\) and \(\xi_1, \ldots, \xi_n \in \kappa\), such that

\((M, \alpha) \in U_{\delta', \xi} \subseteq U\).

Let \(\text{Eq}_\alpha(x_1, \ldots, x_n, y)\) be the formula

\[
\bigwedge \alpha(\xi_i) = \alpha(\xi_j) \land \bigwedge \alpha(\xi_i) = \alpha(\eta_0)
\]

and define \(\delta\) to be \(\delta' \land \text{Eq}_\alpha\). Then obviously

\[(M, \alpha) \in U_{\delta, (\xi, \eta_0)} \subseteq U_{\delta', \xi} \subseteq U\).

Now choose any \((N, \beta), b_1, \ldots, b_n, c\) and \(\eta\) satisfying the hypothesis of part (ii) of the lemma. Then in particular \(N \models \text{Eq}_\alpha(b_1, \ldots, b_n, c)\) and \(c = \beta(\eta)\). Since \(\beta : \kappa \to |N|\) has infinite fibres, we can find \(\zeta_1, \ldots, \zeta_n \in \kappa\) such that \(\beta(\zeta_i) = b_i\), while the sequence \(\zeta_1, \ldots, \zeta_n\) satisfies exactly the same equalities and inequalities as the sequence \(\xi_1, \ldots, \xi_n\). Indeed, if \(\zeta_1, \ldots, \zeta_i\) have been found, and \(\zeta_{i+1} = \zeta_k\) for some \(k \leq i\) or \(\zeta_{i+1} = \eta_0\), then also \(\beta(\zeta_{i+1}) = \beta(\zeta_k)\) or \(\alpha(\zeta_{i+1}) = \alpha(\eta_0)\), hence \(b_{i+1} = b_k\) or \(b_{i+1} = c\) since \(N \models \text{Eq}_\alpha(b_1, \ldots, b_n, c)\). Thus, we can choose \(\zeta_{i+1} = \zeta_k\) respectively \(\zeta_{i+1} = \eta_0\). If, on the other hand, \(\zeta_{i+1} \notin \{\eta_0, \xi_1, \ldots, \xi_i\}\), we can use the fact that \(\beta^{-1}(b_{i+1})\) is infinite, to find \(\zeta_{i+1} = \beta^{-1}(b_{i+1}) \setminus \{\eta, \zeta_1, \ldots, \zeta_i\}\). Thus, there is a permutation \(\pi_1 \in S_\kappa\) with \(\pi_1(\eta) = \eta_0\), \(\pi_1(\xi_1) = \xi_1\), \ldots, \(\pi_1(\xi_n) = \xi_n\). But then \(N \models \delta(b_1, \ldots, b_n, c)\) means that

\[
N \models \delta(\beta(\pi_1^{-1}(\xi_1)), \ldots, \beta(\pi_1^{-1}(\xi_n)), \beta(\pi_1^{-1}(\eta_0))),
\]
or that \(\pi_0(N, \beta) \in U_{\delta, (\xi, \eta_0)}\).

Lemma 4.4. Let \(\eta_0 < \kappa\). There is a cover \(p(\eta_0) = \bigcup_{i \in I(\eta_0)} U_i\) in \(B\), and formulas \(\psi^i_{\eta_0}(y)\), such that for any \(i \in I(\eta_0)\),

(i) \(U_i \subseteq \|\psi^i_{\eta_0}(\eta_0)\|\).
(ii) For any \(\eta < \kappa\), \(\|\psi^i_{\eta_0}(\eta)\| \leq p(\eta)\).
(iii) \(\bigcup_{i \in I(\eta_0)} \|\psi^i_{\eta_0}(\eta_0)\| = p(\eta_0)\).

Proof. Observe that (iii) follows from (i) and (ii). To prove these, write \(U = p(\eta_0)\), and apply Lemma 4.3 to each of the points \((M, \alpha) \in U\). This will give a cover \(U = \bigcup_{i \in I} U_i\) by basic open sets, and for each index \(i\) a formula \(\delta_i(x_1, \ldots, x_n, y)\) and elements \(\xi_1, \ldots, \xi_n < \kappa\) such that

\(U_i = U_{\delta_i, (\xi, \eta_0)}\).
and moreover such that property (ii) of Lemma 4.3 holds for each of these formulas $\delta_i$. Now define

$$\psi_{i_0}^\eta(y) = \exists x_1 \ldots \exists x_n \delta_i(x_1, \ldots, x_n, y).$$

It is now clear that statement (i) in the lemma holds. For (ii), suppose $(N, \beta) \in \downarrow \psi_{i_0}^\eta(\eta)$. This means that

$$N \models \exists x_1 \ldots \exists x_n \delta_i(x_1, \ldots, x_n, \beta(\eta)).$$

By 4.3(ii), we can find $\pi_1 \in S_\kappa$ such that $\pi_1(\eta) = \eta_0$ and $\pi_0(N, \beta) \in U_{\delta_i, (\xi, \eta_0)} = U_i$.

Since $U_i \subset U = p(\eta_0)$, also $\pi_0(N, \beta) \in p(\eta_0)$, and hence, by invariance of $p$, $(N, \beta) \in p(\pi_0^{-1}(\eta_0)) = p(\eta)$, as required. \hfill $\blacksquare$

**Lemma 4.5.** There is a family $\{ \psi_i(y) \mid i \in I \}$ of formulas such that, for all $\eta < \kappa$,

$$p(\eta) = \bigcup_{i \in I} \downarrow \psi_i(\eta).$$

**Proof.** This follows immediately from the previous lemma, for the collection of formulas $\{ \psi_{i_0}^\eta \mid \eta_0 < \kappa, i \in I(\eta_0) \}$. \hfill $\blacksquare$

**Proof of Proposition 4.2.** Consider the function $p' : |M| \to B$ defined by

$$p'(\eta) = \neg p(\eta).$$

Clearly, since $p$ is a predicate, so is $p'$, i.e., $p'(\eta) \land [\eta = \eta'] \leq p'(\eta')$ for all $\eta, \eta' < \kappa$. Moreover, $p'$ is invariant since $p$ is. So we can apply Lemma 4.5 to $p'$, to find a collection of formulas

$$\{ \varphi_j(y) \mid j \in J \}$$

such that for all $\eta < \kappa$,

$$p'(\eta) = \bigcup_{j \in J} \downarrow \varphi_j(\eta).$$

The definability of $p$ now follows by a standard compactness argument. Let $c$ be a “new” constant, and consider the theory

$$T' = T \cup \{ \neg \psi_i(c) \mid i \in I \} \cup \{ \neg \varphi_j(c) \mid j \in J \}.$$

If $T'$ where consistent, it would have a model $M$, which we can assume to be (an expansion of a model) in the set $\delta_T$. Let $\alpha$ be an enumeration of $M$, and choose $\eta < \kappa$ with $\alpha(\eta) = c(M)$, the interpretation of $c$ in $M$. Then $\alpha(\eta) \in X = p(\eta) \lor p'(\eta)$, hence $(M, \alpha) \in \downarrow \psi_i(\eta)$ for some $i \in I$ or $(M, \alpha) \in \downarrow \varphi_j(\eta)$ for some $j \in J$. This means that

$$M \models \psi_i(\alpha(\eta)) \lor \varphi_j(\alpha(\eta)),$$

contradicting the fact that $M$ models $T'$. This proves that $T'$ is inconsistent.

Now apply compactness, to find $i_1, \ldots, i_n \in I$ and $j_1, \ldots, j_m \in J$ such that

$$T \models \forall y (\psi_{i_1}(y) \lor \ldots \lor \psi_{i_n}(y) \lor \varphi_{j_1}(y) \lor \ldots \lor \varphi_{j_m}(y)).$$

Write $\psi = \psi_{i_1} \lor \ldots \lor \psi_{i_n}$ and $\varphi = \varphi_{j_1} \lor \ldots \lor \varphi_{j_m}$. We claim that $\psi$ defines $p$. Indeed, let $(M, \alpha)$ be any point in $X$, and let $\eta < \kappa$. By (10),

$$M \models \psi(\alpha(\eta)) \lor \varphi(\alpha(\eta)).$$
or in other words, either \((M, \alpha) \in \exp{\varphi(q)}\) or \((M, \alpha) \in \exp{\psi(q)}\). If \((M, \alpha) \in \exp{\psi(q)}\), then \((M, \alpha) \in p(q)\) by Lemma 4.2. And if \((M, \alpha) \in \exp{\varphi(q)}\), then \((M, \alpha) \in p^f(q)\) by (9), hence \((M, \alpha) \notin p(q)\). Thus \((M, \alpha) \in \exp{\psi(q)}\) if and only if \((M, \alpha) \in p(q)\).

This shows that \(\exp{\psi(q)} = p(q)\) for any \(\eta < \kappa\), and completes the proof.  

\section{Appendix: Relation to classifying toposes.}

In this appendix we give a topos theoretical interpretation of our Boolean valued model. We assume familiarity with logical aspects of topos theory ([8]).

Using the methods of [3], it is possible to prove the following adaption of Freyd’s theorem [4] for toposes with enough points:

\begin{theorem}
Let \(\mathcal{E}\) be a topos with enough points. Then there exists a topological space \(X_{\mathcal{E}}\) equipped with a continuous group action \(X_{\mathcal{E}} \times H \to X_{\mathcal{E}}\), and an atomic and connected geometric morphism \(\varphi_{\mathcal{E}}: Sh_H(X_{\mathcal{E}}) \to \mathcal{E}\) from the topos of \(H\)-equivariant sheaves over \(X_{\mathcal{E}}\) to \(\mathcal{E}\).
\end{theorem}

As in [3], the construction of the space \(X_{\mathcal{E}}\) and the group \(H\) depends on an object \(G\) in \(\mathcal{E}\) of generators for \(\mathcal{E}\), a set \(P\) of ‘small’ points \(p: \text{Sets} \to \mathcal{E}\) of \(\mathcal{E}\), and a cardinal \(\kappa\) which is an upper bound for the cardinalities \(|p^*G|\) for \(p \in P\). Then \(X_{\mathcal{E}}\) is the topological space of total enumerations of \(G\) with infinite fibres. Unlike the space of partial enumerations used in [3], this space of total enumerations is zero-dimensional (i.e., has a basis of clopen sets). The group \(H\) is \(\text{Aut}(\kappa)\) equipped with the product topology.

This general result can in particular be applied to the classifying topos of a first order theory \(T\) in a language of cardinality \(\lambda'\). Indeed, to \(T\) we associate the Boolean pretopos \(\text{Syn}^b(T)\), the ‘Lindenbaum’ category of equivalence classes of first order formulas with free variables. Two such formulas are equivalent if they are provably equivalent in classical logic (for the intuitionistic variant see [9] or [2]). \(\text{Syn}^b(T)\) carries a natural Grothendieck topology in which finite jointly epimorphic families cover. \(\mathcal{B}^b(T)\) denotes the coherent topos of sheaves on \(\text{Syn}^b(T)\) for this topology. This topos contains a model \(U\) of \(T\), generic with respect to models obeying classical logic in toposes. The space \(X_{\mathcal{B}^b(T)}\) is then precisely the space \(X_T\) of Section 3 of this paper, since the models of cardinality \(\leq \kappa\) induce a set of enough points of \(\mathcal{B}^b(T)\).

Now consider the geometric morphism \(\psi: Sh_H(X_T) \to \mathcal{B}^b(T)\) of the theorem (here \(H = \text{Aut}(\kappa)\)) and the canonical geometric morphism \(\varphi: Sh(X_T) \to Sh_H(X_T)\), induced by forgetting the group action on sheaves. \(M = \varphi^*\psi^*U\) is a sheaf model of \(T\) in \(Sh(X_T)\). Any \(H\)-invariant subsheaf \(P \subset M\) is of the form \(\varphi^*\psi^*\tilde{P}\), for some subsheaf \(\tilde{P} \subset U\), since \(\psi\) is atomic and connected, hence in particular full on subobjects (‘hyperconnected’). If \(P\) is complemented, then both \(P\) and \(\neg P\) are \(H\)-invariant and one can show that \(\tilde{P}\) and \(\neg \tilde{P}\), the subsheaf of \(U\) that is mapped to \(P\) (and \(\neg P\)), is representable. This means that \(\tilde{P}\) belongs to the pretopos \(\text{Syn}^b(T)\), hence is definable.

Finally, since the space \(X_T\) has a clopen basis, the sheaf model \(M\) in \(Sh(X_T)\) as well as the action of the group \(H\) on it can be described purely in terms of the Boolean algebra of clopen subsets of \(X_T\), leading to the explicit description of a model \(\mathcal{M}\) as given in Section 3 above.
