Search for Scalar Charm Quark Pair Production in \( pp \) Collisions at \( \sqrt{s} = 8 \) TeV with the ATLAS Detector

The ATLAS Collaboration

Abstract

The results of a dedicated search for pair production of scalar partners of charm quarks are reported. The search is based on an integrated luminosity of 20.3 \( \text{fb}^{-1} \) of \( pp \) collisions at \( \sqrt{s} = 8 \) TeV recorded with the ATLAS detector at the LHC. The search is performed using events with large missing transverse momentum and at least two jets, where the two leading jets are each tagged as originating from \( c \) quarks. Events containing isolated electrons or muons are vetoed. In an \( R \)-parity-conserving minimal supersymmetric scenario in which a single scalar-charm state is kinematically accessible, and where it decays exclusively into a charm quark and a neutralino, 95\% confidence-level upper limits are obtained in the scalar-charm–neutralino mass plane such that, for neutralino masses below 200 GeV, scalar-charm masses up to 490 GeV are excluded.
Search for Scalar Charm Quark Pair Production in \( pp \) Collisions at \( \sqrt{s} = 8 \) TeV with the ATLAS Detector

The ATLAS Collaboration

The results of a dedicated search for pair production of scalar partners of charm quarks are reported. The search is based on an integrated luminosity of 20.3 fb\(^{-1}\) of \( pp \) collisions at \( \sqrt{s} = 8 \) TeV recorded with the ATLAS detector at the LHC. The search is performed using events with large missing transverse momentum and at least two jets, where the two leading jets are each tagged as originating from charm quarks. Events containing isolated electrons or muons are vetoed. In an \( R \)-parity-conserving minimal supersymmetric scenario in which a single scalar-charm state is kinematically accessible, and where it decays exclusively into a charm quark and a neutralino, 95\% confidence-level upper limits are obtained in the scalar-charm–neutralino mass plane such that, for neutralino masses below 200 GeV, scalar-charm masses up to 490 GeV are excluded.

\( \text{PACS numbers: } 14.80.\text{Ly}, 13.85.\text{Rm} \)

Supersymmetry (SUSY) [1–9] is a theory that extends the Standard Model (SM) and naturally resolves the hierarchy problem by introducing supersymmetric partners of the known bosons and fermions. In the framework of a generic \( R \)-parity-conserving minimal supersymmetric extension of the SM, the MSSM [10–14], SUSY particles are produced in pairs and the lightest supersymmetric particle (LSP) is stable, providing a possible candidate for dark matter. In a large variety of models, the LSP is the lightest neutralino, \( \tilde{\chi}^0_1 \).

The scalar partners (squarks) of various flavors of quarks may, rather generally, have different masses despite constraints on quark flavor mixing [15]. Recent searches disfavor low-mass top squarks (stops), sbottoms, and gluinos, so direct scalar-charm (\( \tilde{c} \)) pair production could be the only squark production process accessible at the LHC. Searches for \( \tilde{c} \) states provide not only a possible supersymmetry discovery mode but also the potential to probe the flavor structure of the underlying theory.

Since no dedicated search for \( \tilde{c} \) has previously been performed, the best existing lower limits on \( \tilde{c} \) masses are obtained from searches for generic squark and gluino production at the LHC [16, 17], and from the reinterpretation of LHC searches [18] for direct pair production of the scalar partner of the top quark followed by decays \( t_1 \rightarrow c + \tilde{\chi}^0_1 \). The top squark searches have a final state similar to that expected for scalar charm quarks, but are optimized for small \( m_{t_1} - m_{\tilde{\chi}^0_1} \) mass differences, and so have good sensitivity to the scalar charm quark only when \( m_c - m_{\tilde{\chi}^0_1} \ll m_W \).

In this Letter, a dedicated search for direct \( \tilde{c} \) pair production is presented. The scalar charm quark is assumed to decay dominantly or exclusively via \( \tilde{c} \rightarrow c + \tilde{\chi}^0_1 \). The expected signal is therefore characterized by the presence of two jets originating from the hadronization of the \( c \) quarks, accompanied by missing transverse momentum (\( E_T^{\text{miss}} \)) resulting from the undetected neutralinos.

The ATLAS detector is described in detail elsewhere [19]. This search uses \( pp \) collision data at a center-of-mass energy of 8 TeV recorded during 2012 at the LHC. After the application of beam, detector and data quality requirements, the data set corresponds to a total integrated luminosity of 20.3 fb\(^{-1}\) with a 2.8\% uncertainty, using the methods of Ref. [20].

The data are selected with a three-level trigger system that required a high transverse momentum (\( p_T \)) jet and \( E_T^{\text{miss}} \) [21]. While events containing charged leptons (electrons or muons) in the search region are vetoed, single-lepton triggers are used for control regions. Events are required to have a reconstructed primary vertex consistent with the beam positions, and to meet basic quality criteria that suppress detector noise and noncollision backgrounds [22]. Jets are reconstructed from three-dimensional topological calorimeter energy clusters by using the anti-\( k_T \) jet algorithm [23, 24] with a radius parameter of 0.4. The measured jet energy is corrected for inhomogeneities and for the noncompensating response of the calorimeter by using \( p_T \) and \( \eta \)-dependent correction factors [26]. The impact of multiple overlapping \( pp \) interactions (pileup) is accounted for using a technique, based on jet areas, that provides an event-by-event and jet-by-jet correction [27]. Only jet candidates with \( p_T > 20 \text{ GeV} \) within \( \eta < 2.8 \) are retained.

Electron candidates are required to have \( p_T > 7 \text{ GeV} \), \( |\eta| < 2.47 \) and to satisfy “medium” selection criteria [28]. Muon candidates are required to have \( p_T > 6 \text{ GeV} \), \( |\eta| < 2.4 \) and are identified by matching an extrapolated inner-detector track to one or more track segments in the muon spectrometer [29]. When defining lepton control regions, muons and electrons must meet additional “tight” selection criteria [29, 30], and must satisfy track and calorimeter isolation criteria similar to those in Ref. [31].

Following this object reconstruction, overlaps between jet candidates and electrons or muons are resolved. Any jet within a distance \( \Delta R = 0.2 \) of a medium quality electron candidate is discarded. Any remaining lepton within \( \Delta R = 0.4 \) of a jet is discarded. Remaining muons
must have longitudinal and transverse impact parameters within 1 mm and 0.2 mm of the primary vertex, respectively. The calculation of $E_T^{\text{miss}}$ is based on the vector sum of the calibrated $p_T$ of reconstructed jets (with $p_T > 20$ GeV and $|\eta| < 4.5$), electrons, muons and photons, and the calorimeter energy clusters not belonging to these reconstructed objects [32].

Jets containing $c$-flavored hadrons without $b$-flavored parent hadrons are identified using an algorithm, optimized for charm tagging, based on a neural network that exploits both impact parameter and secondary vertex information and with a $B$ to $D$ decay chain vertex fitter [33]. This algorithm achieves a tagging efficiency of 19% (13%, 0.5%) for $c$-jets ($b$-jets, light-flavor or gluon jets) in $t\bar{t}$ events. The efficiency for tagging $b$-jets is determined from measurements of dileptonic $t\bar{t}$ events [34]. The $c$-jet tagging efficiency and its uncertainty have been calibrated in inclusive jet events over a range of $p_T$ using jets from collision data containing $D^*$ mesons [35]. Jets can be $c$-tagged only within the acceptance of the inner detector ($|\eta| < 2.5$), so only such central jets are retained after the above selection.

Events are then required to have $E_T^{\text{miss}} > 150$ GeV and one jet with $p_T > 130$ GeV to ensure full trigger efficiency, as well as a second jet with $p_T > 100$ GeV. The two highest-$p_T$ jets are required to be $c$ tagged. The multijet background contribution with large $E_T^{\text{miss}}$, caused by mismeasurement of jet energies in the calorimeters or by neutrino production in heavy-quark decays, is suppressed by requiring a minimum azimuthal separation ($\Delta \phi_{\text{min}}$) of 0.4 between the $E_T^{\text{miss}}$ direction and any of the three leading jets. To reduce the effect of pileup, the third jet is exempted from this requirement if it has $p_T < 50$ GeV, $|\eta| < 2.4$ and less than half of the sum of its track $p_T$ is associated with tracks matched to the primary vertex. In addition, the ratio of $E_T^{\text{miss}}$ to the scalar sum of the transverse momenta of the two leading jets is required to be above one-third. Events containing residual electron or muon candidates are vetoed in order to reduce electroweak backgrounds.

After these requirements, the main SM processes contributing to the background are top quark pair and single top production, together referred to as top production, as well as associated production of $W/Z$ bosons with light- and heavy-flavor jets, referred to as $W+$ jets and $Z+$ jets. A selection based on the boosted-correction transverse mass $m_{CT}$ [36] is employed to further discriminate scalar-charm pair from top production. For two identical decays of heavy particles into two visible particles $v_1$ and $v_2$, and into invisible particles, the transverse mass [37] is defined as $(E_T(v_1) + E_T(v_2))^2 - [p_T(v_1) - p_T(v_2)]^2)^{1/2}$. The boost correction preserves the expected endpoint in the distribution against boosts caused by initial-state radiation. In the case of scalar-charm pair production with $\tilde{c} \to c + \chi_1^0$, $m_{CT}$ is expected to have an endpoint at $(m_{\chi_1^0}^2 - m_c^2)/m_{\tilde{c}}$. For $t\bar{t}$ production, if both $b$-jets are mistagged as $c$-jets, the $m_{CT}$ built using those two jets is expected to have a kinematic endpoint at 135 GeV.

To maximize the sensitivity across the $\tilde{c} \to \tilde{c}^{0}$ mass plane, three overlapping signal regions (SR) are defined: $m_{CT} > 150$, 200, and 250 GeV. The remaining $t\bar{t}$ background after the $m_{CT}$ requirement mostly comprises events with one true $c$-jet from a $W$ decay and a mistagged $b$-jet from a top quark decay. Events in which a $Z$ boson is produced in association with heavy-flavor jets where the $Z$ boson decays into $\nu\bar{\nu}$ also enter the high-$m_{CT}$ regions. The heavy-flavor jets often originate from a gluon splitting, $g \to c\bar{c}$, which can lead to a small angular separation between the resulting $c$-jets and therefore a small invariant mass $m_{cc}$. The remaining $t\bar{t}$ background is also concentrated at low $m_{cc}$. Consequently, a final requirement selects events for which the invariant mass of the two $c$-tagged jets is larger than 200 GeV.

Simulated-event samples are used to aid the description of the background and to model the SUSY signal. Top quark pair and single top production in the $s$ and $Wt$ channels are simulated with POWHEG-1.0 (r2092) [38], while the $t$ channel single top production is simulated using ACERMC 3.8 [39]. A top quark mass of 172.5 GeV is used. The parton shower, fragmentation, and hadronization are performed with PYTHIA-6.426 [40]. Samples of $W+$jets, $Z+$jets, and dibosons ($WW$, $WZ$, $ZZ$) with light and heavy flavor jets are generated with SHERPA 1.4 [41], assuming massive $b/c$ quarks. Samples of $Zt\bar{t}$ and $Wt\bar{t}$ are generated with MADGRAPH-5.1.3.33 [42] interfaced to PYTHIA-6.426. The signal samples are generated for a simplified SUSY model with only a single $\tilde{c}$ state kinematically accessible, and with BR($\tilde{c} \to c + \chi_1^0$)=100$, using MADGRAPH-5.1.5.11 interfaced to PYTHIA-6.427 for the parton shower, fragmentation, and hadronization. Signal cross sections are calculated to next-to-leading order in the strong coupling constant, adding the resummation of soft gluon emission at next-to-leading-logarithm accuracy (NLO+NLL) [43–45]. The uncertainty on each nominal cross section is defined by an envelope of predictions using different PDF sets and factorization and renormalization scales, as described in Ref. [46]. The Monte Carlo (MC) samples are processed through a detector simulation [47] based on GEANT4 [48]. The effects of pileup are included in the simulation. Efficiency corrections derived from the data are applied to the simulation to correct for lepton efficiency as well as the tagging and mistagging rates.

The main SM process contributing to the background after all signal region selections is $Z+$jets, followed by $W+$jets, top quark pair, and single top production. Most $t\bar{t}$ events contributing are $t\bar{t} \to b\bar{b}llqq$ events, in which either a $\tau$ lepton decays hadronically, or an $e$ or $\mu$ is out of the geometric acceptance or not reconstructed or identified. Contributions from multijet, diboson, and associated production of $t\bar{t}$ with $W$, $Z$ are subdominant.
Noncollision backgrounds are found to be negligible.

The estimation of the main background processes is carried out by defining a set of three data control regions (CR) that do not overlap with each other or with the signal regions. The CRs are kinematically close to the SRs and each of them is enhanced in one or two of the backgrounds that is dominant in the SRs, while having low expected signal contamination (less than 1%). A statistical model is set up in which the background expectation in the CRs and SRs depends on several parameters of interest: the normalizations of the dominant backgrounds, top ($t\bar{t} + $ single top), $Z$+jets and $W$+jets, as well as on nuisance parameters including the effect of uncertainties on the jet energy scale (JES) and resolution, calorimeter resolution for energy clusters not associated with any physics objects, energy scale and resolution of electrons and muons, $c$-tagging and mistagging rates, pileup, and luminosity. A profile likelihood fit of the background expectation to the data is performed simultaneously in all luminosity. A profile likelihood fit of the background expectation to the data is performed simultaneously in all CRs [49], and from it the background normalizations are extracted. The normalization factors, which are consistent with unity within uncertainties, are then applied to the MC expectation in the signal regions.

The first control region is populated largely by $t\bar{t}$ and $W$+jets. It contains events with exactly one isolated electron or muon with $p_T$ above 50 GeV. The leading two jets, with $p_T > 130$ and 50 GeV respectively, must be $c$-tagged. To select events containing $W \rightarrow \ell \nu$, the transverse mass of the $(\ell, E_T^{miss})$ system is required to be between 40 and 100 GeV. The upper bound reduces possible signal contamination from SUSY models that produce leptons in cascade decays. Finally, it is required that $E_T^{miss} > 100$ GeV and $m_{CT} > 150$ GeV. The second control region is populated by $Z \rightarrow \ell^+\ell^- \nu\bar{\nu}$ events with two opposite-sign, same-flavor leptons, where the minimum $p_T$ requirement is 70 GeV for the leading lepton and 7(6) GeV for the subleading electron (muon). The transverse momenta of the leptons are added vectorially to the $E_T^{miss}$ to mimic the $Z \rightarrow \ell \ell \nu\bar{\nu}$ decay, and the modulus of the resulting two-vector is required to be larger than 100 GeV. The leading two jets are required to be $c$-tagged and their $p_T$ must each be above 50 GeV. The invariant mass $m_{4\ell}$ of the two leptons is required to be between 75 and 105 GeV ($Z$-mass interval). A third control region, populated almost exclusively by dileptonic $t\bar{t}$ events, contains events with two opposite-sign, different-flavor leptons, where the leading lepton has $p_T > 25$ GeV and the subleading lepton $p_T$ is above 7(6) GeV for electrons (muons). It is required that $E_T^{miss} > 50$ GeV and $m_{4\ell} > 50$ GeV. The leading two jets are required to be $c$-tagged and have $p_T > 50$ GeV. In all CRs, events with additional lepton candidates beyond the required number of signal leptons are vetoed using the same lepton requirements used to veto events in the SRs.

The subdominant background contributions from dibosons, $Zt\bar{t}$ and $Wt\bar{t}$ are estimated by MC simulation. Finally, the residual multijet background is estimated using a data-driven technique based on the smearing of jets in a low-$E_T^{miss}$ data sample with jet response functions [50].

The experimental and theoretical uncertainties affecting the main backgrounds are correlated between control and signal regions, and the data observed in control regions constrain the uncertainties on the expected yields in the signal regions. The residual uncertainty due to the theoretical modeling of the top-production background is about 7%. It is evaluated using additional MC samples generated with AcerMC (where initial- and final-state radiation parameters are varied) an alternative fragmentation model ($\text{HERWIG}$), an alternative generator ($\text{MC@NLO}$), and by using diagram subtraction rather than diagram removal to account for the interference between $t\bar{t}$ and single top $W$-channel production [51]. After the fit, the residual uncertainties on the $W$+jets and $Z$+jets theoretical modeling account for less than 20% of the total uncertainty. The dominant contributions to the residual uncertainty on the total background are from $c$-tagging ($\sim$20%), normalization uncertainties related to the numbers of events in the CRs (10%–20%), and JES (typically 10%–30%).

Table I reports the observed number of events and the SM predictions for each SR. The data are found to be below the SM background expectations, but consistent with them given the uncertainties. Figure 1 shows the measured $m_{CT}$ and $m_{\ell\ell}$ distributions in the $m_{CT} > 150$ GeV region compared to the SM predictions. Monte Carlo estimates are shown after the normalizations extracted from the profile likelihood fit are applied. For illustrative purposes, the distributions expected for the simplified model with $(\tilde{c}, \tilde{\chi}_1^0)$ masses of (400, 200) GeV and (550, 50) GeV are also shown.

Since no significant excesses are observed, the results are translated into 95% confidence-level (C.L.) upper limits on contributions from non-SM processes using the $\text{CL}_s$ prescription [52]. Figure 2 shows the observed and expected exclusion limits at 95% C.L. on the $\tilde{c}\tilde{\chi}_1^0$ mass plane, assuming a single accessible $\tilde{c}$ particle with $\text{BR}(\tilde{c} \rightarrow c + \tilde{\chi}_1^0) = 100\%$. The SR with the best expected sensitivity at each point in the plot is adopted as the nominal result. In the region where the $c$-tagged analysis of the ATLAS $t \rightarrow c + \tilde{\chi}_1^0$ search [18] provides a stronger expected limit, i.e. for $m_{\tilde{c}} - m_{\tilde{\chi}_1^0} \lesssim m_W$, that result is used. The region excluded by the ATLAS monojet search described in Ref. [18] is shown separately as a grey
TABLE I. Expected and observed number of events for an integrated luminosity of 20.3 fb^{-1} at \( \sqrt{s} = 8 \) TeV. Top, Z+jets and W+jets contributions are estimated using the fit described in the text. For comparison, the numbers obtained using MC simulations only are shown in parentheses. The row labeled “Others” reports subdominant electroweak backgrounds estimated from MC simulations. The total uncertainties are also reported.

FIG. 1. Distributions of \( m_{CT} \) (top) and \( m_{cc} \) (bottom), and their corresponding SM predictions. Signal region selections (\( m_{CT} > 150 \) GeV for the \( m_{cc} \) distribution) are applied, other than for the variable plotted. Arrows indicate the SR requirements on \( m_{CT} \) and \( m_{cc} \). In the ratio plots, the grey bands correspond to the combined MC statistical and experimental systematic uncertainty.

FIG. 2. Exclusion limits at 95% C.L. in the \( \tilde{c}\tilde{\chi}_1^0 \) mass plane. The observed (solid red line) and expected (dashed blue line) limits include all uncertainties except for the theoretical signal cross-section uncertainty (PDF and scale). The band around the expected limits show ±1σ uncertainties. The dotted lines around the observed limits represent the results obtained when moving the nominal signal cross section up or down by the ±1σ theoretical uncertainty.
and translate into 95% C.L. upper limits on scalar-charm and neutralino masses in a simplified model with a single accessible $\tilde{c}$ state for which the exclusive decay $\tilde{c} \to c + \tilde{\chi}_1^0$ is assumed. For neutralino masses below 200 GeV, scalar-charm masses up to 490 GeV are excluded, significantly extending previous limits.

We thank CERN for the very successful operation of the LHC, as well as the support staff from our institutions without whom ATLAS could not be operated efficiently.

[25] ATLAS uses a coordinate system with its origin at the nominal interaction point (IP) in the center of the detector and the z-axis along the beam pipe. Cylindrical coordinates ($r, \phi$) are used in the transverse plane, $\phi$ being the azimuthal angle around the beam pipe. The pseudorapidity is defined in terms of the polar angle $\theta$ as $\eta = -\ln (\tan (\theta/2))$, while $\Delta R \equiv [\Delta \eta]^2 + (\Delta \phi)^2]^{1/2}$.

Department of Physics, Oxford University, Oxford, United Kingdom
(a) INFN Sezione di Pavia; (b) Dipartimento di Fisica, Università di Pavia, Pavia, Italy
INFN Gruppo Collegato di Udine, Sezione di Trieste, Udine; ICTP, Trieste; Dipartimento di Chimica, Fisica e Ambiente, Università di Udine, Udine, Italy
Department of Physics, University of Illinois, Urbana IL, United States of America
Department of Physics and Astronomy, University of Uppsala, Uppsala, Sweden
Instituto de Física Corpuscular (IFIC) and Departamento de Física Atómica, Molecular y Nuclear and Departamento de Ingeniería Electrónicay Instituto de Microelectrónica de Barcelona (IMB-CNМ), University of Valencia and CSIC, Valencia, Spain
Department of Physics, University of British Columbia, Vancouver BC, Canada
Department of Physics and Astronomy, University of Victoria, Victoria BC, Canada
Department of Physics, University of Warwick, Coventry, United Kingdom
Waseda University, Tokyo, Japan
Department of Particle Physics, The Weizmann Institute of Science, Rehovot, Israel
Department of Physics, University of Wisconsin, Madison WI, United States of America
Fakultät für Physik und Astronomie, Julius-Maximilians-Universität, Würzburg, Germany
Fachbereich C Physik, Bergische Universität Wuppertal, Wuppertal, Germany
Department of Physics, Yale University, New Haven CT, United States of America
Yerevan Physics Institute, Yerevan, Armenia
Centre de Calcul de l’Institut National de Physique Nucléaire et de Physique des Particules (IN2P3), Villeurbanne, France
Also at Department of Physics, King’s College London, London, United Kingdom
Also at Institute of Physics, Azerbaijan Academy of Sciences, Baku, Azerbaijan
Also at Novosibirsk State University, Novosibirsk, Russia
Also at TRIUMF, Vancouver BC, Canada
Also at Department of Physics, California State University, Fresno CA, United States of America
Also at Department of Physics, University of Fribourg, Fribourg, Switzerland
Also at Tomsk State University, Tomsk, Russia
Also at CPPM, Aix-Marseille Université and CNRS/IN2P3, Marseille, France
Also at Università di Napoli Parthenope, Napoli, Italy
Also at Institute of Particle Physics (IPP), Canada
Also at Particle Physics Department, Rutherford Appleton Laboratory, Didcot, United Kingdom
Also at Department of Physics, St. Petersburg State Polytechnical University, St. Petersburg, Russia
Also at Louisiana Tech University, Ruston LA, United States of America
Also at Institucio Catalana de Recerca i Estudis Avancats, ICREA, Barcelona, Spain
Also at Department of Physics, National Tsing Hua University, Taiwan
Also at Department of Physics, The University of Texas at Austin, Austin TX, United States of America
Also at Institute of Theoretical Physics, Ilia State University, Tbilisi, Georgia
Also at CERN, Geneva, Switzerland
Also at Georgian Technical University (GTU), Tbilisi, Georgia
Also at Ochadai Academic Production, Ochanomizu University, Tokyo, Japan
Also at Manhattan College, New York NY, United States of America
Also at Institute of Physics, Academia Sinica, Taipei, Taiwan
Also at LAL, Université Paris-Sud and CNRS/IN2P3, Orsay, France
Also at Academia Sinica Grid Computing, Institute of Physics, Academia Sinica, Taipei, Taiwan
Also at Laboratoire de Physique Nucléaire et de Hautes Energies, UPMC and Université Paris-Diderot and CNRS/IN2P3, Paris, France
Also at Dipartimento di Fisica, Sapienza Università di Roma, Roma, Italy
Also at Moscow Institute of Physics and Technology State University, Dolgoprudny, Russia
Also at Section de Physique, Université de Genève, Geneva, Switzerland
Also at International School for Advanced Studies (SISSA), Trieste, Italy
Also at Department of Physics and Astronomy, University of South Carolina, Columbia SC, United States of America
Also at School of Physics and Engineering, Sun Yat-sen University, Guangzhou, China
Also at Faculty of Physics, M.V.Lomonosov Moscow State University, Moscow, Russia
Also at National Research Nuclear University MEPhI, Moscow, Russia
Also at Department of Physics, Stanford University, Stanford CA, United States of America
Also at Institute for Particle and Nuclear Physics, Wigner Research Centre for Physics, Budapest, Hungary
Also at Department of Physics, Oxford University, Oxford, United Kingdom

Also at Department of Physics, The University of Michigan, Ann Arbor MI, United States of America

Also at Discipline of Physics, University of KwaZulu-Natal, Durban, South Africa

Also at University of Malaya, Department of Physics, Kuala Lumpur, Malaysia
