SYNTHESIS 1973, 149-151
A New Synthesis of 1,2-Benzocyclohepta-1,3-diene

G. DAUPHIN, L. DAVID, P. DUPRAT, A. KERGOMARD,* and H. VIECHAMBAIRE
Université de Clermont – BP 45 – 63170 – Aubière, France

The recent publication of a new synthesis of homophthalaldehyde¹ (1) prompts us to report the synthesis of 1,2-benzocyclohepta-1,3-diene (3) using a method already described for the cyclization of heptatrienes². o-Allylstyrene (2), obtained from homophthalaldehyde by a Wittig reaction, undergoes cyclization in isopropylamine in the presence of a small amount of suspended sodium to give 1,2-benzocyclohepta-1,3-diene (3) in 55% yield (based on o-allylstyrene). Benzocycloheptene (4) is obtained as a side product in 7% yield³.

The reaction described makes possible the synthesis of 3 from indene in 3 steps, whereas the usual method starting with cinnamaldehyde⁴ requires 4 steps and the method starting with benzosuberone (5) requires two steps.

- After recrystallization from methanol.
- Conversion of starting compound (which was used in large excess).

Conversion of carbonyl compounds used were 0.02 mol for benzophenones and xanthone and 0.1 mol for other compounds.
Sulfurization may be due to nucleophilic attack of these anions on the carbonyl C-atom followed by elimination of $O_2PS^-$ or $OPS^-$ (4), respectively, e.g.

\[
\begin{align*}
R^1\text{C}=O + SPS^- & \xrightarrow{1} R^1\text{C}=S + OP^- \\
R^2\text{C} = O + SPS^- & \xrightarrow{2} R^2\text{C} = S + OP^- \\
R^1\text{C}=O + OPS^- & \xrightarrow{3} R^1\text{C}=S + OP^- \\
R^2\text{C} = O + OPS^- & \xrightarrow{4} R^2\text{C} = S + OP^-
\end{align*}
\]

If $R^1$ or $R^2$ is a good leaving group (as in acid chlorides), no thiono compound (3) is obtained\(^{11}\), probably as a consequence of substitution of the leaving group. For aromatic ketones, the reaction rate is lower when $R^1$ or $R^2$ is electronegative, suggesting that nucleophilic attack of the negative oxygen on phosphorus in the addition product is rate-determining.

In general, the reaction rates are higher in acetonitrile than in the other solvents used (see Table), but the nitrile is not completely inert towards $P_2S_{10}$. During work-up under hydrolyzing conditions, thioacetamide is formed as a side product. With more reactive compounds such as carboxamides, even diethyl ether can be used as a solvent, although it does not give clear solutions with the sulfurizing agent. With esters, except formates, the best yields of thione derivatives are obtained when no solvent and only a catalytic amount of sodium sulfide or hydrogen carbonate is used. We have no explanation for these observations.

Conversion of Carbonyl Compounds into Thiono Compounds; General Procedure:

All sulfurization reactions were performed by dissolving the carbonyl compound in a suitable solvent, adding the solution of $P_2S_{10}$ in the same solvent, and adding solid sodium-hydrogen carbonate to the mixture under stirring and at such a rate as allowed by the evolution of carbon dioxide. Stirring was then continued for several hours. Experimental details are given in the Table. Isolation of the products was performed using several, slightly different procedures:

Isolation Procedure A: The reaction mixture was poured into water. The solid product which separated was isolated by filtration, washed several times with water, and dried at low pressure (0.5 torr) and ~50°.

Isolation Procedure B: Ether was added to the reaction mixture. The ethereal solution was washed several times with aqueous sodium-hydrogen carbonate (5%) and water, dried, and distilled at low pressure.

Isolation Procedure C: The reaction mixture was diluted with ether, filtered, and the filtrate distilled at low pressure.

Isolation Procedure D: Low-boiling reaction products were distilled from residual phosphorus compounds in the reaction mixture at low pressure and collected in a dry-ice trap. They were purified by redistillation.

Using these procedures, the products contained in some cases small amounts (up to 10%) of the starting compound. Pure samples (>95%), however, could be obtained by redistillation or recrystallization. O-Ethyl thioacetate contained some S-ethyl thioacetate, which could not be separated by distillation. To obtain a pure sample, the S-ethyl thioacetate was converted into ethyl dithioacetate via the sulfurization described. Separation of O-ethyl thioacetate and ethyl dithioacetate was possible by distillation.

All products were identified and checked for purity by I.H.-N.M.R. and in the case of aromatic ketones also by I.R. spectrometry. A comparison of the melting and boiling points found with values from the literature is given in the Table.

Mixed Acylals; Synthesis of Alkylidene Carboxylate Formates

J. W. SCHIEREN and W. J. M. TAX

Department of Organic Chemistry, Catholic University, Toernooiveld, Nijmegen, The Netherlands

and R. SCHIRI*

Laboratory of Organic Chemistry, University of Leiden, The Netherlands

Since excellent synthetic procedures for the preparation\(^{1,2}\) of pure mixed anhydrides of formic acid and other carboxylic acids are now available, it appeared worthwhile to investigate the reactivity of these anhydrides towards aldehydes, which might lead to a synthesis of the hitherto unknown mixed alkylidene dicarboxylates of formic acid and other carboxylic acids.
The relevant mixed anhydrides decompose readily at higher temperatures and in the presence of acids and bases. Thus, we performed our first experiments at 0° using iron(III) chloride as a catalyst; formaldehyde was introduced into ethereal solutions of mixed anhydrides. However, the yields of mixed acylals obtained under these conditions were very low due to polymerization of the aldehyde and decomposition (evolution of gas) of the anhydride.

With acetaldehyde, the yields were better (up to 50%), but the reaction mixtures always contained substantial amounts of the ethylidene dicarboxylate with identical acid residues. In some cases, complete separation of this side product from the desired alkylidene carboxylate formate was difficult or even impossible. Ethylene diformate was never found, probably due to its low stability.

Because the use of pure mixed anhydrides did not prevent the formation of acylals with identical acid residues, we modified the procedure, replacing the mixed anhydride by a formic acid-carboxylic acid mixture. It is known that such mixtures contain the mixed anhydride as a consequence of equilibrium (1).

\[
R^2-\text{CHO} + R^1-\text{COOH} \rightleftharpoons R^2-\text{CH}O-C-R^1 + R^1-\text{COOH}
\]

The best results were obtained when the anhydride and formic acid were used in excess (50% and 500%, respectively). If the molar ratio between aldehyde and anhydride is higher, a,a'-acyloxyethers, e.g.

\[
R-C-O-C-R + \text{HCOOH} \rightleftharpoons R-C-O-C-H + \text{R-COOH}
\]

are found as side products.

Among the several possible catalysts tested (FeCl₃, H₂SO₄, P₂O₅, HCOONa, pyridine), phosphorus pentoxide appeared to be the most effective.

The alkylidene carboxylate formates (5) prepared by this procedure are listed in the Table. The compounds were identified and tested for purity by N.M.R. In all compounds, the H₂ peak of

\[
R^2-\text{CH}_2-O-C-R^1
\]

was found between δ = 6.5 and 6.9 ppm (TMS as internal references).

In view of the strong acylating and preferential formylating ability of the formic acid – acetic anhydride system a tentative reaction scheme might be represented as follows.

In Reaction (2), the weaker acid will react more readily than formic acid, though not exclusively. Any alkylidene diformate resulting from the participation of formic acid in Reaction (2) will in any case decompose in the acidic medium; it was never found as side product. The hypothetical intermediate semi-acylal could not be detected (by ¹H-N.M.R. analysis) in the reaction mixture because the equilibrium lies far on the left side, and because compound is used in Reaction (3).

A similar scheme, combining Reactions (2), (4), and (5) but not involving Reaction (3), could explain the formation of a,a'-diacyloxy ethers (7) when the aldehyde is used in excess.

\[
R^2-\text{CH}_2-O-C-R^1 + R^1-\text{COOH} \rightleftharpoons R^2-\text{CH}_2-O-C-R^1 + R^1-\text{COOH}
\]

Preparation of Mixed Acylals; General Procedure:

The carbonyl aphydrate is mixed with formic acid in a molar ratio of 1:5. After standing for 30 min at room temperature, an aldehyde (2/3 equivalents based on anhydride) and phosphorus pentoxide (0.5 g per mol of aldehyde) are added. The mixture becomes warm and a gas is evolved. After the mixture has been left for 3 hr at room temperature, formic acid is evaporated at reduced pressure (15 torr), ether is added, and the ethereal solution is extracted several times with aqueous sodium-hydrogen carbonate and finally with water. The solution is dried with sodium sulfate, ether is evaporated, and the residue is distilled using a Vigreux column (80x1.2 cm). Alkylidene acetate formates free from alkylidene diacetates can only be obtained by distillation of the crude products using a spinning-band column of at least 25 theoretical plates.
