PREPARATION, STRUCTURE AND PROPERTIES OF COMPOUNDS CONTAINING THE DIPOSITIVE TRI-COPPER HEXA(\(N,N\)-DI-\(n\)-BUTYLDITHIOCARBAMATO) ION, COMPOUNDS WITH COPPER IN THE OXIDATION STATES II AND III

BY

J. A. CRAS, J. WILLEMSE, A. W. GAL and B. G. M. C. HUMMELINK-PETERS

(Laboratory for Inorganic Chemistry, University of Nijmegen, Toernooiveld, Nijmegen)

The preparation, some magnetic, spectral and electrochemical properties of the compounds \([\text{Cu}_3(\text{Bu}_2\text{dtc})_6][\text{MBr}_3]_2\) (\(M = \text{Zn}, \text{Cd}, \text{Hg}\)) are reported. The crystal structure of the compound \([\text{Cu}_3(\text{Bu}_2\text{dtc})_6][\text{CdBr}_3]_2\) has been determined by a three-dimensional X-ray analysis. The triclinic cell, space group PI with \(a = 12.629(4)\), \(b = 13.706(4)\), \(c = 12.506(4)\) Å and \(\alpha = 95.84(4)\), \(\beta = 91.45(4)\), \(\gamma = 86.06(3)\)°, contains one formula unit. Atomic parameters were refined to a conventional R value of 0.05 for 1344 independent non-zero reflections. The structure consists of two centrosymmetric ionic units \([\text{Cu}_3(\text{Bu}_2\text{dtc})_6]^{2+}\) and \([\text{Cd}_2\text{Br}_6]^{2-}\). In the cation one copper atom has an apically distorted octahedral S-coordination, with \(\text{Cu—S}\) distances of 2.30(1), 2.35(1) and 3.19(1) Å. The two other equivalent copper atoms have five-fold pyramidal S-coordinations with \(\text{Cu—S}\) distances of 2.21(1), 2.22(1), 2.23(1), 2.23(1) and 2.88(1) Å. The \(\text{Cd}_2\text{Br}_6^{2-}\) ion can be described as a slightly-distorted edge-condensed bitetrahedron. ESR single-crystal spectra prove localisation of the unpaired electron at one copper atom. The I.R. spectra show double \(\text{Cu—S}\) and \(\text{C—N}\) stretching frequencies. All these data suggest the compounds to be composed of copper in different states of oxidation. The cation can be described as \([((\text{Cu}(\text{III})(\text{Bu}_2\text{dtc})_2)_2\text{Cu}(\text{II})(\text{Bu}_2\text{dtc})_2])^{2+}\). The ionic structure is confirmed by conductivity measurements.

Introduction

Compounds with copper in a formal oxidation state of \(+1\frac{1}{2}\) are described in the literature\(^1\) mostly to have copper with equal, indistinguishable oxidation states. The best investigated example in this class of

\(^1\) H. M. McConnel and N. Davidson, J. Am. Chem. Soc. 72, 3168 (1950).
compounds is the dark blue coloured solution, which is obtained when Cu(CH$_3$CN)$_4$ClO$_4$ is added to a solution of Cu(H$_2$O)$_6$(ClO$_4$)$_2$ in acetate-buffered methanol. Esr measurements on this solution at room temperature give a spectrum with seven hyperfine lines ($g = 2.17$, $A = 42G$), indicating that the electron is localised equally on both copper atoms. Mixed valence states of copper atoms, however, are found in the compounds Cu$_3$(NH$_3$)$_4$(CN)$_4$ and Cu$_3$(en)$_2$(CN)$_4$.$^2$ Spectral data of these compounds suggest that in the solid state as well as in highly concentrated solutions, association of [Cu(NH$_3$)$_4$]$^{2+}$ and [Cu(en)$_2$]$^{2+}$ ions with species of copper in the oxidation state +1 exists.

In this publication we report a new series of mixed valence state compounds with copper in the formal oxidation state of $+\frac{2}{3}$ with general formula [Cu$_3$(Bu$_2$dtc)$_6$] [MBr$_3$]$_2$ (M = Zn, Cd, Hg). They were obtained either by the reaction of Cu(bu$_2$dtc)$_2$, MBr$_2$ and Br$_2$ in stoichiometric amounts or by the interaction of 3,5 bis(\(\text{N},\text{N}-\text{dialkyliminium})\)-1,2,4-trithiolane tetrabromo-di-\(\mu\)-bromodicuprate(II), [Bu$_4$bitt] [Cu$_2$Br$_6$]$^3$, and M(Bu$_2$dtc)$_2$.

**Experimental Section**

The starting materials were obtained as described in the literature following the general procedure for the synthesis of dithiocarbamates.$^4$ The preparation of the following compounds is described in the references (Bu$_4$bitt)$^{2-}$, (Cu$_2$Br$_6$)$_{2-}$,$^3$ Cu(Bu$_2$dtc)Br$_2$.$^5$

**Analyses.** Heavy metals were analysed by atomic absorption photometric methods, using dilute aqua regia solutions as standards. The other elemental analyses were carried out in the micro-analytical department of this university.

**Spectra.** Infra-red spectra in the 4000–625 cm$^{-1}$ region were measured on a Perkin-Elmer 257 infrared spectrophotometer. The spectra in the 700–200 cm$^{-1}$ region were measured on a Hitachi-EPI-L instrument. All specimens were recorded in KBr pellets. CsI in the far infrared could not be used because of the oxidation of this compound with the [Cu(Bu$_2$dtc)$_2$]$^+$ complexes. Esr spectra were measured with a Varian V-4503 Q-band spectrometer.

**The magnetic susceptibility** was measured with a standard Gouy-type balance.

---

Electrical conductivity measurements were performed with a Metrohm Konduktoskop E 365 and a Philips PR 9510/00 conductivity cell at 25°C. Different standard solutions of KCl were used for calibration.

Equivalent conductivities were measured for $10^{-4} - 5 \times 10^{-3}$ M solutions of the different compounds. The nitrobenzene was purified by freezing out and vacuum distillation.

Preparation of the Complexes

$[\text{Cu}_3(\text{Bu}_2\text{dtc})_6][\text{MBr}_3]_2 \quad \text{M} = \text{Zn, Cd, Hg.}$

To a suspension of 1 mol $[\text{Bu}_4\text{bitt}]^{2+} [\text{Cu}_2\text{Br}_6]^{2-}$ in chloroform a saturated solution of 2 mol $\text{M(Bu}_2\text{dtc)}_2$ in the same solvent was added. The former compound dissolved slowly and crystalline products could be obtained when petroleum ether (40–60°C) was added to the solution and cooled at 0°C. The compounds were dissolved in chloroform and recrystallized after addition of an equal amount of petroleum ether (40–60°C).

$[\text{Cu(Bu}_2\text{dtc)}_2] [\text{MBr}_3] \quad \text{M} = \text{Zn, Cd, Hg.}$

To a solution of 1 mol $\text{M(Bu}_2\text{dtc)}_2$ in chloroform a solution of 2 mol $\text{Cu(bu}_2\text{dtc)}_2$ in chloroform was added. After addition of an equal volume of petroleum ether (40–60°C) crystalline products were obtained. They were filtered off and washed with petroleum ether (40–60°C).

Once the composition of the products was known, a simpler route to these complexes suggested itself. A mixture of one mol of bromine in chloroform and two mol of $\text{MBr}_2$ dissolved in ethanol was added with stirring to a solution of two or three mol of $\text{Cu(bu}_2\text{dtc)}_2$ in chloroform. Upon addition of petroleum ether (40–60°C) and cooling, precipitates of $[\text{Cu(Bu}_2\text{dtc)}_2] [\text{MBr}_3]$ or $[\text{Cu}_3(\text{Bu}_2\text{dtc})_6][\text{MBr}_3]_2$ respectively, were obtained.

Results and discussion

Magnetic data

Magnetic susceptibility measurements were performed on the compound $[\text{Cu}_3(\text{Bu}_2\text{dtc})_6][\text{CdBr}_3]_2$ in the temperature range 100–293 K. The Curie-Weiss law was followed with a $\Theta$-value of $-10$ K and a molar paramagnetic susceptibility at 293 K of $1500 \times 10^{-6}$ c.g.s. units, corresponding with 1.8 B.M. Measurements on $[\text{Cu}_3(\text{Bu}_2\text{dtc})_6][\text{MBr}_3]_2$ ($\text{M} = \text{Zn and Hg}$) at 293 K gave the values of $\chi_{\text{mol}} = 1650 \times 10^{-6}$ and $1560 \times 10^{-6}$ c.g.s. units, respectively. These values correspond with one unpaired electron. The molar magnetic susceptibility of $[\text{Cu(Bu}_2\text{dtc)}_2][\text{HgBr}_3]$ was found to be $-360 \times 10^{-6}$ c.g.s. units, which is very close to the sum of the diamagnetic susceptibilities of the constituent atoms ($-420 \times 10^{-6}$ c.g.s. units).

* Tables of the elemental analyses of the compounds investigated, as well as the atomic parameters, structure factors and bond angles and distances of the butyl chains of the compound $[\text{Cu}_3(\text{Bu}_2\text{dtc})_6][\text{Cd}_2\text{Br}_6]$, are available on request.
Esr spectra of the compounds \([\text{Cu}_3(\text{Bu}_2\text{dtc})_6] [\text{MBr}_3]_2 \) \((\text{M} = \text{Zn}, \text{Cd}, \text{Hg})\) were measured at room temperature on powder samples as well as on solutions in chloroform. In the powder spectrum four equidistant lines could be observed on the low-field side, the high-field part of the spectrum was not resolved due to the broadness of the lines. Preliminary results\(^6\) from single-crystal measurements at room temperature showed four broad lines in all directions. The derived principal g-values were \(g_1 = 2.0907(2), g_2 = 2.0252(2), g_3 = 2.0205(2)\) and the principal hyperfine values were \(A_z = 154.8(1), A_y = 43.1(7)\) and \(A_x = 26.0(7) \times 10^{-4} \text{ cm}^{-1}\). These values correspond well with those found by Weeks and Fackler\(^7\) for a solid solution of monomeric \(\text{Cu}(\text{Et}_2\text{dtc})_2\) in \(\text{Ni}(\text{Et}_2\text{dtc})_2\) with principal g-values of \(2.084(0.5), 2.025(1), 2.020(1)\) and principal A-values of \(159(1), 42(2.5)\) and \(36(2.5) \times 10^{-4} \text{ cm}^{-1}\). Because of the broadness of the lines, only the low-field part of the powder spectrum, \(i.e.\) the part corresponding with the highest g-value, could be interpreted. The values of \(g_x\) and \(A_z\) determined from this part of the spectrum were in good agreement with those determined from the single-crystal spectra. Although in these compounds delocalisation of the unpaired electron at more than one copper atom would be expected, the principal values of g and A suggest the electron to be localised on one copper atom only.

Esr spectra of chloroform solutions are identical with those of \(\text{Cu}(\text{Bu}_2\text{dtc})_2\) in chloroform.

**Infrared Spectra**

In Table I some absorption frequencies of the compounds are given. In the complexes \([\text{Cu}(\text{Bu}_2\text{dtc})_2] [\text{MBr}_3] \) \((\text{M} = \text{Zn}, \text{Cd}, \text{Hg})\) the given absorption frequencies are about the same as those in \(\text{Cu}(\text{Bu}_2\text{dtc})_2\text{I}_3\). The increase in the C—N stretching frequency of about 12 cm\(^{-1}\) is probably due to the effect of the anion the location of which has a distinct influence on the electron density on the nitrogen. The \(\text{I}_3^-\)-anion is located at a van der Waals bonding distance \((4 \text{ Å})\) from the nitrogen atom\(^9\), so increasing the positive charge of this atom, which causes a higher C—N bond order. The non-linear anions \(\text{MBr}_3^-\) are not likely to be located at such a short distance from the nitrogen atom and do not have any effect on the C—N bond order. The same effect is found in

the complexes [Au(R$_2$dtc)$_2$]$^+$X$^-$ where X$^-$ stands for different anions$^{10}$. Only one Cu-S frequency is tentatively assigned.

Comparison of the infrared spectra of the compounds [Cu(Bu$_2$dtc)$_2$] [MBr$_3$] with those of the [Cu$_3$(Bu$_2$dtc)$_6$]$^{2+}$-complexes shows the latter to have two strong absorption frequencies in the 1500–1550 cm$^{-1}$ region, while two absorption peaks are present also in the 350–400 cm$^{-1}$ region. The latter bands could arise from a Cu-S stretching mode. X-ray data show two different Cu sites to be present in these complexes, esr data indicate them to be Cu(II) and Cu(III). Given this it is reasonable to assign the lower of the C—N stretching frequencies as belonging to the Cu(II)(Bu$_2$dtc)$_2$ unit, the higher to the Cu(III)(Bu$_2$dtc)$_2$ unit. In the same way the lowest Cu-S frequency could belong to the Cu(II) unit, the highest to the Cu(III) moiety of the compounds.

The values show a slight increase in the Cu(II)-S stretching frequency in the [Cu$_3$(Bu$_2$dtc)$_6$] [MBr$_3$]$_2$ complexes with respect to Cu(II)-(Bu$_2$dtc)$_2$ and a slight decrease in the Cu(III)-S frequency with respect to the Cu(III) complexes. This could indicate a decreased electron density on the Cu(II) atom and an increased electron density on the Cu(III) atoms, both leading to a too low effect to be seen in the bond length determined in the crystallographic studies. The effect however can also be ascribed to the difference in symmetry present in the [Cu$_3$(Bu$_2$dtc)$_6$] [MBr$_3$]$_2$ compounds and the compared Cu(II) and Cu(III) complexes.

Powdering a 2:1 mixture of [Cu(Bu$_2$dtc)$_2$] [MBr$_3$] and Cu(Bu$_2$dtc)$_2$

yielding the complex $[\text{Cu}_3(\text{Bu}_2\text{dtc})_6][\text{MBr}_3]_2$. Hence summation spectra had to be obtained by superposition of the separate spectra in the correct concentrations.

The metal-bromine frequencies are not observable above $200 \text{ cm}^{-1}$ if the metal is cadmium or mercury. A fairly strong band is found at $241 \text{ cm}^{-1}$ in the complexes containing $\text{ZnBr}_3^-$. This absorption is much more intense than the absorptions found in the $230-250 \text{ cm}^{-1}$ region of the cadmium and mercury complexes. So we tentatively assign this frequency to be a Zn-Br stretching frequency.

**Conductivity Measurements**

The equivalent conductivities of the different compounds were measured in nitrobenzene. Following the procedure, described in a previous paper\(^\text{11}\), the concentration dependencies are expressed by the Onsager limiting law

$$\Lambda = \Lambda_0 - \Lambda_0 \sqrt{c} = \Lambda_0 - (\alpha_0 + \beta) \sqrt{c}$$

By plotting $\Lambda$ as a function of $\sqrt{c}$ we found for the compounds under investigation the values for $\Lambda_0$, $\Lambda_{\text{exp}}$ and $\Lambda_{\text{calc}}$ as given in Table II.

<table>
<thead>
<tr>
<th>$\Lambda_0$</th>

<td>75</td>
</tr>
</tbody>
</table>

The value of $\Lambda_{\text{calc}}$ for $[\text{Cu}_3(\text{Bu}_2\text{dtc})_6][\text{CdBr}_3]_2$ was obtained assuming this complex to be a $1:2$ electrolyte. The dimeric nature of the bromocadmate ion is confirmed by the X-ray structure determination of the compound. The experimental values of $\Lambda_0$ and $\Lambda_{\text{exp}}$ for the compounds $[\text{Cu}(\text{Bu}_2\text{dtc})_2][\text{HgBr}_3]$, $[\text{Cu}_3(\text{Bu}_2\text{dtc})_6][\text{ZnBr}_3]_2$ and $[\text{Cu}_3(\text{Bu}_2\text{dtc})_6][\text{HgBr}_3]_2$, are normal for $1:1$ electrolytes. So the conclusion can be

drawn that in nitrobenzene the former compound is fully dissociated into the ions Cu(Bu₂dtc)²⁺ and HgBr₃⁻, the latter complexes in a neutral Cu(Bu₂dtc)₂ molecule, two Cu(Bu₂dtc)²⁺ ions and two MBr₃⁻ (M = Zn, Hg) ions.

**Crystal data**

The compound bis[bis(N,N-di-η-butyldithiocarbamato)copper(III)] bis(N,N-di-η-butyldithiocarbamato)copper(II)tetrabromo-di-μ-bromo-dicadmate(II), F.W. 2121.13 crystallizes as dark violet-black needles. Weissenberg photographs showed the crystals to be triclinic. From platinum calibrated Weissenberg photographs, using CuKα radiation (λ = 1.5418 Å) application of a least-squares procedure yielded the unit cell dimensions a = 12.629(4), b = 13.706(4), c = 12.506(4) Å; α = 95.84(4), β = 91.45(4), γ = 86.03° and V = 2148.0(5) Å³. The density Dₓ = 1.6346 g cm⁻³ was determined by the flotation method. The calculated density, Dx, is 1.6404 g cm⁻³ with Z = 1.

A crystal of approximate dimensions 0.07 × 0.07 × 0.2 mm³ was mounted with needle axis (110) along the φ-axis of a Nonius automatic diffractometer. Intensity data were measured with Zr-filtered Mo-radiation using the moving-counter moving-crystal method with a scan speed of 1.2° min⁻¹. After every 14 reflections a reference reflection was measured to allow corrections to be made for fluctuations in the measuring performance.

Of the 4000 independent reflections theoretically attainable within the limit Θ = 20°, 1344 reflections were used for the structure determination.

Absorption corrections (linear absorption coefficient μ = 45.0, maximum influence 1.34, minimum influence 1.30 in the intensities) were calculated by the Busing and Levy¹² procedure using 4 × 4 × 10 volume components and 10 accurately located boundary planes. Lorentz and polarisation corrections were performed in the usual way, and the presumed standard deviations σ (Fₒ) of the structure amplitudes were derived from σ (I) = σ_c, where σ_c is the counting statistical error.

**Structure Determination**

The positions of the cadmium, bromine and copper atoms were determined from a three-dimensional Patterson function. Two subsequent

---

difference Fourier syntheses, assuming the structure to be centrosymmetric, gave the positions of the remaining non-hydrogen atoms. The positional and vibrational parameters were refined in two diagonal blocks in alternating cycles. The first block contained the positional and the anisotropic temperature parameters of cadmium, bromine, copper and sulfur, and the scaling factor, the second block the positional and isotropic vibrational parameters of nitrogen and carbon and the scaling factor. The function that was minimized was $\Sigma w(|F_o| - |F_c|)^2$ with weight $w = (\sigma^2(F_o) + 0.05|F_o|)^{1/2}$ $^{13}$. The atomic scattering factors were those of Cd, Br$^-$, Cu for Cu(II) and Cu$^+$ for Cu(III), S, N and C corrected for the anomalous scattering component ($\Delta f'$) using data from the International Tables$^{14}$. The final R-value was 0.05 for the 1344 observed reflections.

Description of the Structure

The structure is illustrated in Fig. 1. Bond angles and distances of the important atoms are given in Fig. 2.

---

The crystal structure analysis revealed the compound to be composed of two centrosymmetric ions \([\text{Cu}_3(\text{Bu}_2\text{dtc})_6]^{2+}\) and \([\text{Cd}_2\text{Br}_6]^{2-}\). The cation contains three \(\text{Cu}(\text{Bu}_2\text{dtc})_2\) units. One of these units is planar centrosymmetric with \(\text{Cu}-\text{S}\) distances which are not significantly different from those in \(\text{Cu}(\text{Et}_2\text{dtc})_2\) 2.317(2), 2.297(2), 2.301(2) and 2.339(2) Å. The other two equivalent \(\text{Cu}(\text{Bu}_2\text{dtc})_2\) units are slightly pyramidally deformed planes with much shorter \(\text{Cu}-\text{S}\) distances, which are the same as those in \([\text{Cu}(\text{Bu}_2\text{dtc})_2]^{+} \text{I}_3^-\) 2.23(2), 2.22(2), 2.21(2) and 2.22(2) Å. From these data it is justifiable to conclude that in the first unit copper has the formal oxidation state +2 and in the second unit it has the formal oxidation state +3.

The three units are piled at remarkably short distances: \(\text{Cu(III)}-\text{S}\) 2.88 Å and \(\text{Cu(II)}-\text{S}\) 3.19 Å. Therefore the coordination of \(\text{Cu(III)}\) can be described as distorted square pyramidal and that of \(\text{Cu(II)}\) as distorted octahedral. The structure of the complex cation can be compared with that of nickel dithiobenzoate\(^{16}\) in which three units are also stacked in a B-A-B order. The B-type unit in that compound also seems to have a deviation of planarity, although the deviations are not given by the authors. The Cu atom in the B-type unit of our compound has a deviation of the least-squares plane, defined by the atoms \(\text{S}_3\text{S}_4\text{S}_5\text{S}_6\),

of 0.266(4) Å. The pyramidal coordination of this Cu(III) is noteworthy for a $d^8$ configuration. The structure of the anion is comparable with that of the Hg$_2$I$_6^2^-$ ion in the complex [Et$_4$bit$]^{2+}$[Hg$_2$I$_6$]$_2$$^2^-$ and can be described as a slightly-distorted edge-condensed bitetrahedron. All interionic contacts are in the expected range.
