in the spectrum of the reaction mixture having reacted overnight (see above), are assigned to the N—CH₃ and the H—C= signals of 9 (R¹ = H), respectively. This was confirmed when after an overnight reaction the ¹H-NMR spectra of the solutions of 1b, 1c and 1d in N₂D₄ D₂O were measured. In the case of 1c and 1d in the low field region a peak is observed between δ 7.03-7.09 i.e. the CH₃ in 9 (R¹ = H) where in the case of 1b this low-field singlet is absent but a peak is observed in the high field region at δ 1.87 i.e. the CH₃ in 9 (R¹ = CH₃)¹³.

The three pyrazoles 8b, 8c and 8d which were isolated from the analogous reaction of the pyrimidinium salts 1b, 1c and 1d, are all deuterated at position 4. It was observed further that the 3,5-dimethyl-4-D-pyrazole (8c) also contains deuterium in the methyl group as proved by the presence of peaks at m/e = M, M + 1, M + 2, M + 3, M + 4 and M + 5 in the mass spectrum. Apparently, in the open-chain compounds 3, 4 and 5 the methyl group participates in the tautomerism since the alternative possibility – a H/D exchange in the methyl group of 3,5-dimethyl-4-D-pyrazole – does not take place under these mild conditions.

Experimental part

The ¹H-NMR spectra were recorded on a Jeol JNM-C60 H spectrometer, using TMS (δ = 0) as internal standard. In the case of adduct measurements the apparatus was equipped with a JES-VT-3 variable temperature controller. Measurements of D contents were carried out on an AEI-MS 902 mass spectrometer.

Preparation of the starting materials

1-Methylpyrimidinium iodide (1a), 1,2-dimethylpyrimidinium iodide (1b), 1,4,6-trimethylpyrimidinium iodide (1c) and 4-phenyl-1-methylpyrimidinium iodide (1d) were prepared as described in the literature.

General procedure for measuring the ¹H-NMR spectra in N₂D₄ D₂O

To 50 mg of the quanterized compound 1 being cooled at ~ -30°C about 0.5 ml of precooled (~ -30°C) deuterated hydrazine hydrate (Merck, 80% N₂D₄ D₂O, deuteration ratio >99%) was added. A yellow-orange coloured solution was obtained. TMS was added as internal standard. A sample of this solution was introduced in a ¹H-NMR tube being cooled at ~ -30°C. The measurements started 10-15 min after addition. The pyrazoles 8a-d being obtained in the hydrazinolysis were isolated as described previously.

One of the authors (M. S. Brouwer) wishes to thank the management of Philips Duphar B.V., Weesp, The Netherlands, for giving him the opportunity to carry out this work at the Laboratory of Organic Chemistry, Agricultural University, Wageningen, The Netherlands. We are indebted to Drs. C. A. Landheer for measuring the mass spectra.

Poly(iminomethylenes). 7¹ Synthesis of diphenylphosphine-substituted poly[(1-phenylethyl)iminomethylene]

A. J. Naaktgeboren, R. J. M. Nolte and W. Drenth

Department of Organic Chemistry of the University, Croesestraat 79, Utrecht, The Netherlands (Received August 31st, 1977)

Abstract. Polymer-anchored phosphine functions were obtained in two ways: by diphenylphosphination of poly[(1-(4-bromophenylethyl)iminomethylene] and by polymerization of 1-[4(diphenylphosphino)phenyl]-1-isocyanooethane. The synthesis of the monomers and polymers is described.

Introduction

Many efforts have been made at anchoring homogeneous catalysts on insoluble supports. For this purpose materials like silica² and polystyrene³-⁸ have frequently been used. This immobilization of a catalyst sometimes diminishes side-reactions⁵ and extends its lifetime. The anchoring of homogeneous catalysts on the usual types of polymeric supports suffers from a number of disadvantages. In most cases the secondary structure of the polymers and the surroundings of the catalytic centres are unknown. Often, the accessibility of the complexes is reduced, giving rise to lower activities. The degree of introduction of phosphine groups, often used as interfaces between polymer and metal ion, appears to be low: 1 per 3-20 polymer side chains⁷-⁸. Moreover, the polymers usually contain some

residual chlorine or bromine. In earlier papers Millich\(^\text{19,20}\) and we\(^{21,22}\) showed that poly(iminomethylenes) have the configuration of a tightly coiled helix with side-chains protruding from a rodlike main chain. This property gives poly(iminomethylenes) major advantages for catalyst attachment: the catalytic centres are more accessible and the secondary structure is more uniform and better defined. The chirality of the main chain might be attractive for asymmetric catalysis.

In this paper we describe the synthesis of two types of triphenylphosphine containing poly(iminomethylenes). The first type was made by diphenylphosphination of poly(1-(4-bromo-phenyl)ethyl)iminomethylene\(^\text{14}\) to estimate the molecular composition. The second type was synthesized by polymerization of a triphenylphosphine containing isocyanide. Applications of these polymers in catalysis will be described in subsequent papers of this series.

**Results and discussion**

Millich has described the synthesis of 1-phenylethyl isocyanide and its polymerization by means of an acid-coated glass catalyst\(^\text{12}\). We have synthesized 1-(4-bromophenyl)-ethyl isocyanide, (3), in an analogous way starting from cyanide and its polymerization by means of an acid-coated catalysis will be described in subsequent papers of this series. The isocyanide 3 was polymerized in a yield of 75-85% by dehydration of 9 using either phosphoryl chloride or perchloromethyl formate\(^\text{17}\), both in combination with triethylamine. Direct synthesis of 10 from isocyanide 3 by reaction with butyllithium and chlorodiphenylphosphine gave unsatisfactory results.

The pale-yellow crystals of 10 were moderately soluble in ethanol and diethyl ether, and soluble in tetrahydrofuran, acetone, chloroform and dichloromethane. In chlorinated hydrocarbons slow decomposition was observed. In the infrared spectrum of 10 strong absorptions were visible at 2142 and 1430 cm\(^{-1}\) indicative of the isocyanide and phenylphosphine functions. The structures of 10 and its precursors 8 and 9 were supported by elemental analysis, \(^{1}H\), \(^{13}C\) and \(^{31}P\)-NMR and mass spectroscopy.

The isocyanide 10 was readily polymerized with treatment with nickel chloride. After isolation and fractionation, polymer 11 was obtained as a light yellow powder. The polymer was soluble in tetrahydrofuran, chloroform, benzene and toluene, and insoluble in the lower alcohols. The intrinsic viscosity of 11 was determined from the elongation of a tightly coiled helix with side-chains protruding from a rodlike main chain. This property gives poly(iminomethylenes) major advantages for catalyst attachment: the catalytic centres are more accessible and the secondary structure is more uniform and better defined. The chirality of the main chain might be attractive for asymmetric catalysis.

**Scheme 2**

Protection of the carbonyl function in 4-bromoacetophenone, 1, by 1,2-ethanediol gave the acetal 6. Its product of lithiation can be used as a synthon for coupling with many types of reagent. Reaction of this synthon with chlorodiphenylphosphine gave the substituted triphenylphosphine 7. This compound was hydrolyzed to give 8 which was directly converted to N-formyl[1-(4-diphenylphosphino)phenyl]ethylamine, 9, via a Leuckart synthesis\(^\text{15}\). Initial attempts to synthesize 9 through reaction of the Grignard or lithium derivative of 2 with chlorodiphenylphosphine failed. The isocyanide 10 was obtained in a yield of 75-85% by dehydration of 9 using either phosphoryl chloride or perchloromethyl formate, both in combination with triethylamine. Direct synthesis of 10 from isocyanide 3 by reaction with butyllithium and chlorodiphenylphosphine gave unsatisfactory results.

\(\text{a}\) Reaction conditions 5a: 1.3 eq. BuLi, reaction time 2 h; 3.2 eq. Ph\(_2\)PCl, reaction time 4 h; 5b: 2.1 eq. BuLi, reaction time 3 h; 7.2 eq. Ph\(_2\)PCl, reaction time 96 h.

\(\text{b}\) \(m\), \(n\) and \(o\) are the fractions of unsubstituted, bromine substituted and phosphone substituted phenyl groups, respectively.

Just like functionalized polystyrene resins, polymer 5 suffers from two disadvantages: the distribution of phosphorus over the polymer chain is unknown and the presence of bromine can affect the behaviour of the support, e.g. by quaternization of phosphine with a possibility of cross-linking\(^\text{3}\). Therefore, we decided to synthesize also a poly(iminomethylene) with a phosphine function in each repeating unit (Scheme 2).
weight in the range of 5,000–10,000. Usually, a molecular weight of 40,000–50,000 is found after polymerization of other isocyanides under these conditions. The lower values found for 11 might result from steric hindrance of polymerization by the bulky triphenylphosphine group.

Experimental part

Proton NMR spectra were obtained on Varian EM 360 and EM 390 spectrometers. The 13C- and 31P-spectra were recorded on a Varian CFT 20 and a Bruker WH 90 spectrometer, respectively. Elemental analyses were carried out by the Elemental Analytical Section of the Institute for Organic Chemistry TNO under supervision of W. J. Buis. NMR chemical shifts, δ, are given in ppm downfield from internal tetramethylsilane, unless otherwise stated.

Abbreviations used are: s = singlet, d = doublet, t = triplet, q = quartet, m = multiplet, br = broad and dist = distorted. All solvents and reagents were dried and distilled under a nitrogen atmosphere.

4-Bromoacetophenone (1) was synthesized in 82% yield in accord with the literature11). 'H-NMR (CCl4): 2.50 (s, 3H, CH3), 4.70 (q, 1H, CH), 7.10 and 7.40 (2 x d, 10J = 7.2 Hz, 14H, arom.).

- The chemical shifts are in ppm relative to tetramethylsilane; the 13C—31P coupling constants are in Hz.
- The numbering of the carbon atoms is as follows:

![Carbon Numbering]

- The 13C resonance of the C=O carbon is at 160.82.
- The 13C resonance of the isocyanide carbon was not observed.

2 ml of water. This mixture was shaken for 30 minutes, water was decanted and the solution was concentrated. Crystallization from ethanol afforded 0.38 g (80%) of 8; m.p. 106-108°; IR (KBr): 3300-2300 (NH), 1750 (C=O), 1580 (arom.), 1500 (CH=CH), 1470 and 1390 (CH3), 1430 (P—Ph), 830 (1,4-disubst. arom.), 745 and 700 (monosubst. arom.) cm⁻¹. For the 13C-NMR spectrum see Table II.

N-Formyl[1-[4-(diphenylphosphino)phenyl]ethyl]amine (9). This formamide was synthesized from 7 via a Leuckart synthesis.15 To 34.8 g (0.10 mol) of 7 were added, 100 ml of formamide, 25 ml of formic acid and 2 ml of water. This mixture was kept overnight; the solution was heated to 180-190° and at regular intervals 20 ml portions of formic acid were added and water was distilled off. In this way 10 portions were added during 25 hours of heating. This procedure was followed by addition of two portions of 25 ml of toluene at a temperature of 200°. After cooling, the solution was poured into 400 ml of water/diethyl ether/THF (1:1:1 v/v). The solution was filtered, decanted and the solution concentrated. Crystallization from cold water and with 75 ml of a 7.5% NaHCO3 solution. The di­

By warming slightly an amount of 2.36 g (7.5 mmol) of crystallized 10 was dissolved in 8 ml of an ethanolic solution which contained 9 mg (0.5 mol %) of nickel chloride hexahydrate. The solution was stirred for four days at room temperature and the resulting suspension centrifuged; after decantation of the supernatant liquid the solid was twice suspended in methanol and isolated by centrifugation. Drying in vacuo (30°, 0.01 mm) afforded 1.65 g (70%) of polymer 11 as a light yellow powder. It was dissolved in 10 ml of THF, fractionated over a deactivated silica column and eluted with THF/ethanol (10:1, v/v); yield 1.60 g. The first fraction (1.30 g) was dissolved in 10 ml of THF and added drop by drop to 200 ml of pure methanol, which was stirred rapidly. The resulting suspension was centrifuged and the supernatant liquor decanted. After drying in vacuo (35°, 0.005 mm) 1.19 g of 11 was collected; [γ] = 0.04 dl/g (toluene, 30.0°); (C21H20NOP) (315.3); calc. C 79.98, H 5.75, N 4.47, P 9.72; found C 79.98, H 5.75, N 4.47, P 9.72, no oxygen or water. For the 1H-NMR spectrum see Table II.

The iso­cyanide 10 was synthesized from 9 in two ways. The first method was analogous to the synthesis of 3; yield 70%. The second method used perchloromethyl formate17; to 16.6 g (0.05 mol) of 9 and 10.7 g (0.11 mol) of triethylamine in 50 ml of dichloromethane were added 4.85 g (0.025 mol) of perchloromethyl formate in 30 ml of dichloromethane at a temperature of —10° during one hour. Stirring was continued for one hour while the temperature was allowed to rise to 20°. The solution was rapidly washed with 50 ml of cold water and with 75 ml of a 7.5%; NaHCO3 solution. The dichloromethane solution was rapidly concentrated in vacuo (20°, 10 mm) and the residue dissolved in dry THF. This solution was dried over molisieve 4A, filtered and concentrated in vacuo (20°, 1 mm). The yield was 12.9 g (82%) of a yellow-brown solid. The solid was crystallized from ethanol (highest temp. 35°). The light yellow crystals were dried in vacuo (20°, 0.03 mm); m.p. 84.0-85.3°. According to elemental analysis the crystals contained ethanol: (C₄H₅N[P]O₂) (329.2); found C 75.4, H 6.2, N 4.5, P 8.96; IR (KBr): 3200, 1810, 1710 (C=O), 1580 (arom.), 1480 and 1400 (CH3), 1430 (P—Ph), 825 (1,4-disubst. arom.), 745 and 695 (monosubst. arom.) cm⁻¹. For the 1H-NMR spectrum see Table II.

Poly[[[1-[4-(diphenylphosphino)phenyl]ethyl]iminomethylene]11]. By warming slightly an amount of 2.36 g (7.5 mmol) of crystallized 10 was dissolved in 8 ml of an ethanolic solution which contained 9 mg (0.5 mol %) of nickel chloride hexahydrate. The solution was stirred for four days at room temperature and the resulting suspension centrifuged; after decantation of the supernatant liquid the solid was twice suspended in methanol and isolated by centrifugation. Drying in vacuo (30°, 0.01 mm) afforded 1.65 g (70%) of polymer 11 as a light yellow powder.
