Erratum to: Dynamics of gene silencing during X inactivation using allele-specific RNA-seq

Hendrik Marks, Hindrik H. D. Kerstens, Tahsin Stefan Barakat, Erik Splinter, René A. M. Dirks, Guido van Mierlo, Onkar Joshi, Shuang-Yin Wang, Tomas Babak, Cornelis A. Albers, Tüzer Kalkan, Austin Smith, Alice Jouneau, Wouter de Laat, Joost Gribnau and Hendrik G. Stunnenberg

After the publication of this work [1], we noticed there was an error in Fig. 5 where −1.0 and 1 are incorrectly displayed in the y-axis in panel b. Please see the corrected Fig. 5 below. We apologize for this error.

References
**Fig. 5** Allele-specific RNA-seq on three NPC lines identifies three distal regions of genes that escape XCI. 

**a** Ratio of Xi/Xa (y-axis; for each of the three NPC lines sorted from highest to lowest) for genes showing a log2 ratio of at least $-5$. We set the cutoff for escape on 10% relative expression from the Xi versus the Xa (log2 ratio of $> -3.32$; similar to Yang et al. [37]).

**b** Xi/Xa ratio of genes that escape XCI in all three NPC lines.

**c** Distribution of the escape genes identified in *NPC_129-Xi* over the four clusters as characterized in Fig. 4a. The black dots on the fourth row represent all X-linked genes for which high-confidence allele-specific ratios were obtained in NPCs.

**d** Localization of the escape genes within each NPC line over the linear X chromosome (see also Table 1). The black dots on the fourth row represent all X-linked genes for which high-confidence allele-specific ratios were obtained in NPCs.

**e** Validation of the escape genes within the three escape regions by Sanger sequencing of cDNA. See Additional file 1: Figure S13 for the full panel of 13 genes that we validated, and for further details.
