Abstract—1. Infusions of ovine prolactin for 10 days induced hypercalcemia in unfed American eels, Anguilla rostrata LeSueur, that tentatively was related to stimulation of branchial Ca\(^{2+}\)-uptake mechanisms.

2. Analysis of ATPase activities in the plasma membranes of the branchial epithelium in prolactin treated eels showed a specific stimulation of high-affinity Ca\(^{2+}\)-ATPase.

3. The results of this study form further evidence that the high-affinity Ca\(^{2+}\)-ATPase activity represents the Ca\(^{2+}\)-pump of the branchial epithelium.

INTRODUCTION

Fish can regulate their serum calcium levels with great precision (Bailey and Fenwick, 1975; Copp and Ma, 1978) and this ability must be attributed, at least in part, to the capacity of their gills to absorb calcium directly from their aquatic environment (Berg, 1968; Simmons, 1971; Simkiss, 1974; So and Fenwick, 1977; Payan et al., 1981). Unfortunately, there is a paucity of information concerning the mechanisms of this branchial calcium uptake.

Recently we reported the simultaneous occurrence of non-specific phosphatase activity and high-affinity Ca\(^{2+}\)-ATPase activity in American eel gill plasma membranes (Flik et al., 1983, 1984). Further, we equated the heterogeneous non-specific phosphatase activity with the Ca\(^{2+}\)-activated ATPase activity which has been reported present in the gills of many teleostean species and which has been described as related to calcium transport (Ma et al., 1974; Fenwick, 1976; Moon, 1978; Fenwick, 1979; Ho and Chan, 1980; Doneen, 1981). However, the characteristics of this activity more closely resemble those of an alkaline phosphatase rather than a transport Ca\(^{2+}\)-ATPase (Ghijsen et al., 1980). On the other hand, we identified the branchial high-affinity Ca\(^{2+}\)-ATPase as a calmodulin-sensitive ATPase that was stimulated by intracellular Ca\(^{2+}\)-concentrations in the presence of excess Mg\(^{2+}\) (Flik et al., 1984). These characteristics suggested that it was this latter activity which is associated with the branchial Ca\(^{2+}\)-pump in fish.

The present study was directed towards testing the effect of ovine prolactin on both the Ca\(^{2+}\)-dependent phosphatase and the high-affinity Ca\(^{2+}\)-ATPase in American eel gill plasma membranes to determine which, if either, of the activities respond to prolactin treatment.

Prolactin is known to induce hypercalcemia in several species of fish (Pang et al., 1978; Wendelaar Bonga and Flik, 1982), including American eel (Copp et al., 1982). It was further reported that ovine prolactin enhanced calcium influx in perfused American eel gills (Ma and Copp, 1981). The rationale behind our present study was that if prolactin stimulates gill calcium absorption it should stimulate enzymic activities associated with active calcium transport.

MATERIALS AND METHODS

Adult female yellow eels, Anguilla rostrata LeSueur, with an average body weight of 1.7 kg were obtained from a commercial dealer in Quebec City, Quebec, Canada. The eels were held in running dechlorinated Ottawa tapwater (0.45 mM Ca\(^{2+}\), 12°C) with 16 hr of light alternating with 8 hr of darkness. The animals were not fed.

Hormone treatment

Ovine prolactin was kindly supplied by the Hormone Distribution Agency of the National Institutes of Health, Bethesda, MD and was administered continuously for 10 days by means of Alzet osmotic minipumps implanted intraperitoneally. The dosage was 0.1 U/g fish/day, dissolved in 0.05 N HCl. Controls received equivalent amounts of solvent. Ovine prolactin, at the doses used in this study,

Generally mimics homologous prolactin in its effects on osmoregulation and Ca\(^{2+}\)-metabolism of fish (Wendelaar Bonga and Van der Meij, 1980). At the end of the experiment the infusion rates of the pumps were checked by measuring the pump contents (maximum infusion duration of the pumps approximated 19 days at 12°C) and a maximum deviation of 10% was accepted. The stabilility of the hormone preparation was checked electrophoretically by comparison of freshly dissolved prolactin with prolactin recovered from the pumps at the end of the experiment. Silver stained electrophoregrams did not reveal any differences. Control and experimental animals were individually marked by fin clipping and were kept in the same tank during the experiment.

At the end of the experimental period the eels were anesthetized in a Tris-buffered (pH 7.4) MS222 solution and the blood was collected into heparinized tuberculin syringes by direct cardiac puncture. After centrifugation of the blood, total plasma Ca was estimated with a commercial Ca kit (Sigma, 586-A), Mg analyzed by atomic absorption spectrophotometry, and Na and K by flame emission spectrophotometry, and Na and K by flame emission spectrophotometry, and Na and K by flame emission spectrophotometry, and Na and K by flame emission spectrophotometry.

Isolation of branchial plasma membranes and enzyme assays

Plasma membranes were isolated and assayed for protein, succinic dehydrogenase, Na\(^{+}/K^{+}\)-ATPase, Ca\(^{2+}\)-ATPase and high-affinity Ca\(^{2+}\)-ATPase activities as described previously (Flik et al., 1983, 1984). Statistical analysis of the results was carried out applying Student's t-test (two-sided, z = 5%.)

RESULTS

Blood plasma analysis

Prolactin treatment of eels increased plasma calcium levels significantly from 2.84 ± 0.17 mM in controls to 3.40 ± 0.20 mM (P < 0.01). Plasma total Mg levels were significantly decreased after this treatment (P < 0.01). No significant differences in plasma Na, K or P, levels were observed (Table 1).

Enzyme analyses

Prolactin treated eels showed a statistically significant increase in high-affinity Ca\(^{2+}\)-ATPase specific activity (measured as the 1 μM Ca\(^{2+}\) induced Mg \= ATP hydrolysis). Neither Na\(^{+}/K^{+}\)-ATPase nor Ca\(^{2+}\)-ATPase-phosphatase activities were affected by this treatment. Succinic dehydrogenase specific activities in whole tissue homogenates and in the enriched plasma membrane fractions of control and prolactin treated fish did not differ significantly and were similar to values reported for untreated eels (Flik et al., 1983). The amounts of total protein extracted from the gills and recovered in the plasma membrane fraction were not significantly different for control and experimental fish.

In these plasma membrane fractions calculated total high-affinity Ca\(^{2+}\)-ATPase activities were 13.4 μmole P\(_i\)/hr for controls and 21 μmole P\(_i\)/hr for prolactin treated eels (57% stimulation). Total Na\(^{+}/K^{+}\)-ATPase activities were 157.2 and 170.8 μmole P\(_i\)/hr controls and experimentals, respectively. Ratios for total Na\(^{+}/K^{+}\)-ATPase to high-affinity Ca\(^{2+}\)-ATPase were 11.7 for controls and 8.1 for prolactin treated eels, indicating a 44% stimulation of high-affinity Ca\(^{2+}\)-ATPase activity relative to Na\(^+\)/K\(^+\)-ATPase activity in branchial plasma membranes after prolactin treatment (Table 2).

DISCUSSION

Prolactin and blood plasma mineral composition

Ovine prolactin induced hypercalcemia in fresh water yellow eels and this result agrees with earlier findings from killifish (Pang et al., 1978), sticklebacks (Wendelaar Bonga and Greven, 1978), the tilapia Sarotherodon mossambicus (Wendelaar Bonga and Flik, 1982; Wendelaar Bonga et al., 1983) and American eels (Ma and Copp, 1981). In addition, prolactin induced hypomagnesemia, a phenomenon also reported earlier for tilapia (Wendelaar Bonga et al., 1983). In mammals such a hypomagnesemia is considered to be a direct effect of the concomitant hypercalcemia (Ebel and Guenther, 1980). Prolactin did not affect plasma Na, K or P, levels, which indicates the specific nature of the hypercalcemic action of prolactin under these conditions. Ma and Copp (1981) have shown for American eels, the species used in this study, that this effect can be ascribed to stimulation by prolactin of Ca\(^{2+}\)-uptake in the gills.

Prolactin and branchial ATPase activities

Prolactin enhanced high-affinity Ca\(^{2+}\)-ATPase activities in the plasma membranes of eel branchial epithelium, which suggests that prolactin may influence Ca-metabolism by activating a Ca\(^{2+}\)-pump in the gills. Prolactin did not stimulate the non-specific Ca \~ ATP-phosphatase activity. We take these observations as evidence that it is the high-affinity Ca\(^{2+}\)-ATPase and not the non-specific phosphatase which functions as a Ca\(^{2+}\)-transporting enzyme. Further, the recovery of branchial total Na\(^{+}/K^{+}\)-ATPase, total Ca \~ ATP-phosphatase and total protein were similar in prolactin treated and control eels. The absence of an effect on either the Ca \~ ATP-phosphatase or the Na\(^{+}/K^{+}\)-ATPase activities indicates that the action of prolactin on the gills is not of a general trophic character. This is also supported by the fact that the ratios of total Na\(^{+}/K^{+}\)-ATPase to total high-affinity Ca\(^{2+}\)-ATPase differed between prolactin treated and control eels. The decrease of the ratio from 11.7 in the controls to 8.1 in prolactin treated eels suggested a specific induction of high-affinity Ca\(^{2+}\)-ATPase in branchial plasma membranes.

Interestingly, our results show some close simi-
laries with data published by Ghijsen and Van Os (1982) on rat intestine. These authors reported that 1α,25(OH)2 vitamin D3 specifically stimulated a transport Ca2+-ATPase, that resembles the eel branchial Ca2+-ATPase closely, but not Na+/K+-ATPase in enterocytes from vitamin D3-repleted rachitic rats; the ratios for Na+/K+-ATPase to transport Ca2+-ATPase activities amounted to 11.6 in the controls and 7.1 in 1α,25(OH)2 vitamin D3-repleted animals. Using rachitic rats, Pahuja and DeLuca (1981) showed that also prolactin directly influences intestinal Ca absorption in a way comparable to 1α,25(OH)2 vitamin D3; these authors concluded that the action of prolactin was independent of the vitamin D endocrine system.

In conclusion, it is our opinion that prolactin is involved not only in the control of branchial permeability for water and ions (Wendelaar Bonga and Van der Meij, 1981; Wendelaar Bonga et al., 1983), but also in the regulation of the branchial Ca2+-pump. This contention may contribute new ideas to the discussion on the role of prolactin in hydromineral balance of fresh water teleosts.

Acknowledgements—The authors are greatly indebted to Mrs Lise Belanger and to Mr Frans Wilms for their excellent assistance during the experiments. Experiments were carried out in the department of Biology, University of Ottawa and were supported by a NSERC of Canada operating grant (No. A6246) to Dr J. C. Fenwick.
