Evidence for P2-purinoceptor-mediated uptake of Ca2+ across a fish (Oreochromis mossambicus) intestinal brush border membrane

Peter H. M. KLAREN*, Sjoerd E. WENDELAAR BONGA and Gert FLIK†

Department of Animal Physiology, Faculty of Science, University of Nijmegen, Toernooiveld, 6525 ED Nijmegen, The Netherlands

We have studied the effect of ATP on Ca2+ uptake in intestinal brush border membrane vesicles (BBMVs) of the teleost tilapia (Oreochromis mossambicus). ATP stimulated Ca2+ uptake 12-fold over the control, with a linear time course. Ionomycin and detergent treatment did not reduce BBMVs's Ca2+ content, indicating the binding of Ca2+ to a membrane component. A rank order of ATP > ADP > AMP was established for the stimulation of Ca2+ uptake. Adenosine, vanadate, adenosine 5'-[a,β-methylene]triphosphate (a P2x purinoceptor agonist) and adenosine 5'-[γ-thio]triphosphate (a P-type ATPase inhibitor) were without effect. 2-Methylthioadenosine 5'-triphosphate, a P2x purinoceptor agonist, mimicked the stimulation by ATP. As judged from a kinetic comparison, ATP hydrolysis and the stimulation by ATP of Ca2+ uptake were not compatible. The P2 purinoceptor antagonist suramin and the P2x purinoceptor antagonist Reactive Blue-2 inhibited the Ca2+ uptake stimulated by 1 mM ATP (IC50 0.17 mM and 58 μM respectively). We conclude that ATP-stimulated Ca2+ uptake in tilapia intestine is disassociated from ATPase activity and is mediated through a P2 purinoceptor.

INTRODUCTION

Extracellular ATP-stimulated Ca2+ influx has been demonstrated in many different cell types, including ovarian tumour cells, smooth-muscle cells, cells from HL-60, HeLa and NG108-15 lines, J774 mouse macrophages, rat thyroid cells and atrial myocytes [1–8]. The literature on ATP-stimulated Ca2+ uptake in intestinal cells is scarce; stimulatory effects of ATP in isolated enterocytes from human colon and from rat and chicken intestine have been reported [9–11]. A P2 purinoceptor [10], an ATP-activated, protein kinase-regulated ion channel [11] and a Ca2+ uptake system sensitive to prenylamine (an antagonist for calmodulin) [9] have been advanced to explain the stimulation by ATP of Ca2+ uptake in these cells. Unfortunately, observations on isolated cells do not allow discrimination between the apical and basolateral membrane domains as the site where ATP interacts with the Ca2+ transport system. Proceeding from the stimulatory effect of extracellular ATP on Ca2+ uptake in isolated enterocytes [9–11], and from the observation that millimolar concentrations of a nucleoside triphosphate occur in tilapia intestinal mucosal fluid, we here focus on the hypothesis that ATP regulates Ca2+ entry across the apical membrane of the enterocyte. Purified brush border membrane vesicles (BBMVs) were used as a tool. We provide evidence for an ATPase-independent, ATP-stimulated Ca2+ uptake in intestinal BBMVs and conclude from pharmacological studies that a subtype of a P2 purinoceptor is present in the apical membrane of the enterocyte and is involved in Ca2+ uptake.

MATERIALS AND METHODS

Animals

Sexually mature tilapia (Oreochromis mossambicus) of both sexes, weighing 250–450 g, were obtained from laboratory stock. Fish were kept in 100-litre aquariums, supplied with running Nijmegen water ([Ca2+] 0.8 mM, at 25 °C) under a photoperiod of 16 h of light alternating with 8 h of darkness. The animals were fed with Trouvit® commercial fish food (Trouw, Putten, The Netherlands), at a ration of 1.5 % (w/w) of their body weight per day.

Materials

CaCl2 was purchased from Amersham International (Aylesbury, Bucks., U.K.). Scintillator 299® was from Packard Instrument Co. (Meriden, CT, U.S.A.). ATP (Tris salt), adenosine 5'-[a,β-methylene]triphosphate (pp[CH2]pA) and ADP [di(monicyclohexylammonium) salt] were from Sigma Chemical Co. (St. Louis, MO, U.S.A.). AMP (free acid) and adenosine 5'-[γ-thio]triphosphate (ATP[S]) were from Boehringer (Mannheim, Germany). Reactive Blue-2 and the tetrasodium salt of 2-methylthioadenosine 5'-triphosphate (2-MeSATP) were from Research Biochemicals International (Natick, MA, U.S.A.). SK&F 96365 (dissolved in DMSO) was kindly provided by Dr. R. J. M. Bindels (Department of Physiology, Faculty of Medicine, University of Nijmegen, Nijmegen, The Netherlands). Suramin was a gift from Bayer AG (Leverkusen, Germany). Solutions of suramin were made in ultrapure water and were prepared freshly before experimentation. All chemicals were of analytical grade and obtained from commercial suppliers. Membrane protein was determined with a Coomassie Brilliant Blue kit (Bio-Rad, München, Germany), with BSA as a reference.

Isolation of intestinal brush border membranes

Fish were killed by spinal transection, and intestinal brush border membranes were isolated by using a magnesium aggregation technique and differential centrifugation as described in detail previously [12]. Brush border membranes were collected in 150 mM KCl/0.8 mM MgCl2/20 mM Hepes/Tris (pH 7.4). The final membrane preparation was enriched 17-fold in alkaline phosphatase (EC 3.1.3.1). We previously determined that almost 100 % of the vesicles are oriented right-side-out [12].

Abbreviations used: BBMV, brush border membrane vesicle; pp[CH2]pA, adenosine 5'-[a,β-methylene]triphosphate; ATP[S], adenosine 5'-[γ-thio]triphosphate; 2-MeSATP, 2-methylthioadenosine 5'-triphosphate.

Ca\(^{2+}\) transport assays

Zero trans \(\text{Ca}^{2+}\) uptake

The assay medium was identical with the buffer in which the membranes were suspended and contained calculated free concentrations of 5 mM \(\text{Ca}^{2+}\) and 0.8 mM \(\text{Mg}^{2+}\), and graded amounts of total nucleotide. The \(\text{Ca}^{2+}\) concentration used in our assays was in the range of the ambient intestinal luminal concentration, which we measured to range from 2 to 27 mM. \(\text{Ca}^{2+}\) uptake in the presence of a fixed nucleotide concentration was measured at 1 mM nucleotide. This concentration represents \(V_{\text{max}}\) conditions with respect to ATP, as measured by ATP hydrolysis in a 5 min assay. The \(^{45}\text{Ca}^{2+}\) radioactive concentration was 2.5 MBq/ml. Assays were performed at 37 °C; membranes and assay media were prewarmed before incubation. The incubation temperature chosen was the optimum for another important \(\text{Ca}^{2+}\) transporting protein in fish, namely the high-affinity \(\text{Ca}^{2+}\)-ATPase [13]. We calculate that in the presence of 1 mM total ATP, 96% of the ATP is complexed with \(\text{Ca}(0.72\text{ mM CaATP}^2^-)\) or \(\text{Mg}(0.24\text{ mM MgATP}^2^-)\), leaving a free ATP\(^4-\) concentration of 35 \(\mu\text{M}\). Incubation was initiated by mixing 10 \(\mu\text{l}\) of a preparation of BBMVs with 70 \(\mu\text{l}\) of the assay medium. Zero trans \(\text{Ca}^{2+}\) uptake was measured as the difference between uptake for 5 min at 37 °C and at 0 °C. SK&F 96365 was tested at a concentration of 15 \(\mu\text{M}\), which is in the range of the IC\(_{50}\) values reported for different preparations [7,14,15]. Suramin is generally employed at concentrations equal to or higher than the agonist concentration [2,16,17]. We added suramin at 0.1 and 1.0 mM to the assay medium. Reactive Blue-2 was added at concentrations ranging from 30 to 500 \(\mu\text{M}\). All antagonists were tested with 1 mM ATP present in the incubation medium. The reaction was quenched by the addition of 1 ml of ice-cold isotonic stop buffer containing 150 mM KCl, 20 mM Trizma-7.0 (pH 7.4 at 0 °C) and 10 mM \(\text{LaCl}_3\). The quenched sample was immediately filtered over an 80 kPa vacuum, using ME25 nitrocellulose filters with a pore size of 0.45 \(\mu\text{m}\) (Schleicher & Schuell, Dassel, Germany). Filters were rinsed three times with 2 ml of the ice-cold stop buffer and dissolved in 4 ml Scintillator 299* scintillation cocktail. The radioactivity retained on the filters was measured in a Microfluor Centaur centrifuge to obtain a clear supernatant on which the assay was performed. The assay is based on the phosphorylation of 3-phosphoglycerate by ATP and the subsequent conversion of 1,3-diposphoglycerate to glyceraldehyde 3-phosphate, during which reaction NADH is oxidized to NAD\. The decrease in NAD\(^{+}\) content of the reaction mixture is then a measure of the initial ATP content of the sample. A solution containing 1 mM ATP was run in parallel with the intestinal samples and served as a standard. According to the manufacturer's information, the ATP-diagnostic kit is equally sensitive to the nucleoside triphosphates GTP, ITP and UTP. We therefore refer to the results of this assay as nucleoside triphosphate levels. A method in which a firefly luciferase–luciferin reagent was employed proved unsuitable for the detection of ATP in luminal samples because of the turbidity of the samples, luminescence could not be detected even after the addition of an internal ATP standard.

Calculations and statistics

To calculate free and complexed Ca, Mg and ATP concentrations in our assay media we used the computer program Chelator [19]. Stability constants were from Sillén and Martell [20]. Data points from inhibition studies were fitted to the equation:

\[
v = v_0 \left[1 - \frac{[I]}{[I]K_i}\right]
\]

where \(v_0\) is the uptake rate in the absence of the inhibitor, \([I]\) is the inhibitor concentration and \(K_i\) is the value of \([I]\) at which inhibition is half-maximal under the specific incubation conditions. Data were analysed with a nonlinear regression data analysis program [21]. Results are presented as means ± S.E.M. unless stated otherwise. Student's \(t\)-test for unpaired data and Welch's approximate, and Kruskal-Wallis' non-parametric, analysis of variance followed by Dunn’s multiple comparison test were used for statistical evaluation as appropriate. Significance was accepted at \(P < 0.05\). Asterisks indicate a significant difference with respect to the control (*\(P < 0.05\), **\(P < 0.01\), ***\(P < 0.001\)).

RESULTS

The average nucleoside triphosphate concentration in the luminal fluid of tilapia was 0.9 ± 0.3 mM (\(n = 9\)).

Figure 1 shows a linear time course of the ATP-stimulated zero trans \(\text{Ca}^{2+}\) uptake. A slope of 55 nmol/min per mg is calculated. The tracer content of the BBMVs was not affected by the addition of 10 \(\mu\text{M}\) ionomycin/1 % Triton X-100, indicating the binding of \(\text{Ca}^{2+}\) to membrane components. In contrast, in control incubations (i.e., in the absence of extracellular ATP) the addition of ionomycin resulted in a 2-fold increase in the
Involvement of a P, receptor in Ca\textsuperscript{2+} uptake in fish intestine

Figure 1  Time course of ATP-stimulated zero trans Ca\textsuperscript{2+} uptake in tilapia intestinal BBMVs (means ± S.E.M., n = 5)

Effects of 10 \mu M ionomycin and 1% Triton X-100 in the extravesicular medium are shown. The B Ca\textsuperscript{2+} concentration was 5 mM. Symbols: ○ △ □ controls (i.e. uptake in the absence of ATP). Arrows indicate the addition of ionomycin (△ □) and Triton X-100 (□ ■) respectively. ○ ● ● Controls (untreated membranes). The slope of the straight line indicates an uptake rate of 55 nmol/min per mg.

Figure 2  ATP-stimulated 45Ca\textsuperscript{2+} uptake, measured in a 5 min incubation interval, plotted as a function of protein concentration in the membrane vesicle preparation

The 45Ca in the BBMVs is expressed as a fraction of the specific radioactivity of the tracer. The straight line is described by the function \( y = 4.3 \times 10^{-2} x - 3 \times 10^{-3} \) (r = 0.69, n = 23, \( P = 0.0003 \)). A runs test did not indicate a significant departure from linearity (\( P = 0.36 \)).

Figure 3  Effect of 1 mM ATP cis on isotope equilibrium exchange rate (n = 4)

Means ± S.E.M. are shown. Isotope exchange rate in the presence of 1 mM ATP cis can be described by a straight line with a slope of 68 nmol/mg. Symbols: ○, uptake in the presence of 1 mM ATP cis; ●, controls.

\( ^\dagger \) Suramin (1 mM) significantly inhibits ATP-stimulated Ca\textsuperscript{2+} uptake (\( P = 0.04 \)).

trar content in BBMVs. Here, Triton X-100 treatment, in disrupting the vesicular osmotic space, caused the tracer content to fall just below zero.

Figure 2 shows that the ATP-stimulated Ca\textsuperscript{2+} uptake is linearly correlated with the protein concentration in the preparation of BBMVs (\( r = 0.69, P = 0.0003 \)), indicating a relation between the stimulated Ca\textsuperscript{2+} uptake and a component of the membrane vesicle preparation.

In our experimental set-up the ATP-stimulated Ca\textsuperscript{2+} uptake is measured as a temperature-sensitive uptake. This approach is common in many membrane transport studies and is used to distinguish non-specific binding of tracer to extravesicular sites from transmembrane translocation. Ca\textsuperscript{2+} uptake at 0°C and in the presence of 1 mM ATP was 31 ± 3% (\( n = 23 \)) of the total uptake measured at 37°C; 70% of the ATP-stimulated Ca\textsuperscript{2+} uptake is thus temperature-dependent. Compared with control BBMVs, at 0°C 1 mM ATP increased the Ca\textsuperscript{2+} content in BBMVs by a factor of 1.9 ± 0.2 (\( n = 21 \)). At 37°C this increase was a factor of 11.8 ± 1.7 (\( n = 23 \)), again showing temperature dependence. We further investigated extravesicular Ca\textsuperscript{2+} binding by using an isotope equilibrium exchange protocol. During the loading procedure, vesicles are not only loaded intravesicularly (as validated in a previous paper [12]), but it can also be assumed that extravesicular binding sites will be masked by Ca\textsuperscript{2+}. Figure 3 shows that 1 mM ATP in the extravesicular medium produces a linear rate of tracer equilibrium exchange, compared with control incubations. From the knowledge that the specific vesicular volume of the BBMVs is 6.0 μl/mg it can be calculated that from a vesicular Ca\textsuperscript{2+} content of 30 nmol/mg intravesicular loading takes place. These results are best explained by assuming...
the exposure of intravesicular Ca\(^{2+}\)-binding sites on incubation with ATP.

ATP, ADP and AMP (1 mM) stimulated Ca\(^{2+}\) uptake in BBMVs, albeit with a decreasing amplitude (Table 1). Adenosine was without effect. Vanadate (10 \(\mu M\)), an inhibitor of P-type ATPases, and SK&F 96365 (15 \(\mu M\)), an antagonist of receptor-mediated Ca\(^{2+}\) entry [15], did not inhibit ATP-stimulated Ca\(^{2+}\) uptake in BBMVs.

From the results obtained so far it seems that an adenosine phosphoesterase is important in the uptake of Ca\(^{2+}\) in BBMVs. Because ATPase activity has been localized to the apical membrane mammalian intestinal cells [22–27], an investigation of the involvement of an ATPase in the uptake of Ca\(^{2+}\) was warranted.

In the presence of inhibitors of (Na\(^{+}\)+K\(^{+}\))-ATPase and alkaline phosphatase activity, BBMVs showed a nucleotidase activity, hydrolysing ATP and ADP (Figure 4). Apparent affinity coefficients (\(K_{m}\)) were 88 \(\mu M\) ATP and 230 \(\mu M\) ADP respectively. Because AMP did not affect transport (Table 1) we did not assay AMP hydrolysis by BBMVs. When BBMVs were incubated at pH 10.2 and with a zinc supplementation, i.e. under optimal conditions for alkaline phosphatase, the potency rank order was reversed: AMP ADP ATP (results not shown). Because all of the BBMVs preparation is oriented right-side-out [12], the nucleotidase activity must be an extracellular activity in the enterocyte. These results could indicate that hydrolysis of a phosphate ester is necessary to cause the stimulatory effect of ATP. We therefore examined the kinetics of ATP hydrolysis and the ATP concentration dependence of Ca\(^{2+}\) uptake in BBMVs. Both experiments were performed under conditions that yielded initial velocities. Figures 5(A) and 5(B) show that the kinetics of these processes, measured in paired preparations, differed significantly. ATP hydrolysis was well described by single Michaelis–Menten kinetics (Hill coefficient 1.0). The kinetic parameters \(V_{\text{max}}\) and \(K_{m}\) were calculated to be 82 \(\mu M\) and 64 \(\mu M\) ATP respectively. In the same substrate range, the ATP-stimulated Ca\(^{2+}\) uptake was linear, having a slope of 60 \(\mu l/min\) per mg and an offset representing ATP-independent uptake (as described previously [12]). These results show that ATP hydrolysis is not responsible for the ATP-stimulated Ca\(^{2+}\) uptake in BBMVs. The free ATP\(^{4-}\) concentration in our assay media can be calculated from the total ATP concentration. The inset in Figure 5(B) shows that, up to 180 \(\mu M\) free ATP\(^{4-}\) (which is equivalent to 5 mM total ATP in our assay medium), Ca\(^{2+}\) uptake is also a linear function of the ATP\(^{4-}\) concentration.

We finally tested the involvement of an ATP receptor. Incubations of BBMVs with 1 mM suramin, a \(P_{2y}\) purinoceptor antagonist, resulted in a significant decrease in the ATP-stimulated Ca\(^{2+}\) uptake (Table 1). From Table 1 a \(K_{i}\) of 0.17 mM suramin was calculated. An ATP analogue of which the adenine base is modified (2-MeSATP, a \(P_{2y}\) agonist) mimicked the stimulatory effect of ATP (Table 1). Analogues with modifications in the triphosphate chain (ATP[S] and pp(CH\(_{2}\))pA) were unable to stimulate Ca\(^{2+}\) uptake in BBMVs (Figure 6). The \(P_{2y}\) antagonist Reactive Blue-2 dose-dependently inhibited the ATP-stimulated Ca\(^{2+}\) uptake (Figure 6). A \(K_{i}\) of 58 \(\mu M\) was calculated.

The curve is described by a single Michaelis–Menten equation. The inset shows an Eadie–Hofstee transformation of the data. Kinetic parameters are: \(V_{\text{max}} = 82 \mu M\) of P\(_{i}\)/h per mg, \(K_{m} = 64 \mu M\) ATP, Hill coefficient 1.0.

(B) ATP-dependent Ca\(^{2+}\) uptake in tilapia intestinal BBMVs. Means ± S.E.M. (\(n = 3\)). Slope and intercept of the straight line are 60 \(\mu l/min\) per mg and 19 nmol of Ca\(^{2+}\)/min per mg respectively. The inset shows Ca\(^{2+}\) uptake as a function of the calculated free ATP\(^{4-}\) concentration. Slope and intercept of the straight line in the inset are 2 \(\mu l/min\) per mg and 19 nmol of Ca\(^{2+}\)/min per mg respectively.
Involvement of a P₂ receptor in Ca²⁺ uptake in fish intestine

![Graph showing dose-dependent inhibition by Reactive Blue-2 of ATP-stimulated Ca²⁺ uptake in intestinal brush border membranes. The extravesicular ATP concentration was 1 mM. Kᵢ is calculated as 58 μM Reactive Blue-2.](image)

**DISCUSSION**

We conclude from this study that a P₂ purinoceptor located in the apical membrane of the enterocyte is involved in ATP-stimulated Ca²⁺ transport in tilapia intestinal BBMVs. The kinetics of ATP-stimulated Ca²⁺ uptake and ATP hydrolysis by ecto-ATPase activity proved incongruent. Consequently we rejected an adenosine (ecto)nucleotidase activity as a mediator of the ATP-stimulated Ca²⁺ transport. For Ca²⁺ uptake in tilapia BBMVs we established an agonist rank order of ATP = 2'-MeSATP > ADP > AMP. Adenosine, ATP[S] and pp[CH₇]pA were ineffective in stimulating Ca²⁺ uptake. Ca²⁺ uptake was a linear function of ATP² concentration, and this is indicative of a P₂ subtype purinoceptor. However, it has been reported that ADP and AMP are ineffective in stimulating P₂ receptors [28].

There is a consensus [28–30] on the non-subtype-specific inhibitory action of suramin on P₃X and P₃ receptors, the insensitivity of P₃ receptors for pp[CH₇]pA and the sensitivity of the P₃ subtype for 2-MeSATP and Reactive Blue-2. Our results therefore seem to be congruent with a P₃ subtype purinoceptor’s [28–31] mediating Ca²⁺ transport in tilapia intestine. However, the pharmacological profile (i.e. inhibition by Reactive Blue-2 and stimulation by 2-MeSATP) of a recently cloned P₃ purinoceptor [32] is similar to that of a cloned P₃ purinoceptor [29]. For this reason, and because of possible differences between mammalian and non-mammalian purinoceptors, further experiments are needed to obtain a definite subtyping of the P₃ purinoceptor. The compound SK&F 96365, an antagonist for receptor-mediated Ca²⁺ entry (RMCE), failed to block the ATP effect. SK&F 96365 blocks L-type voltage-operated Ca²⁺ channels in smooth-muscle cells and pituitary GH₃ cells [15] and an ATP-stimulated Ca²⁺ current in human neutrophils [7]. However, in a smooth-muscle preparation SK&F 96365 failed to inhibit ATP-gated Ca²⁺ channels [15]. It has been concluded that SK&F 96365 modulates post-receptor events, i.e. the Ca²⁺ entry step rather than receptor binding of the agonist [15].

ATP and ATP analogues have been reported to act on the smooth musculature of the gastrointestinal tract of several teleost species [33–36]. Knight and Burnstock [37] were the first to demonstrate the involvement of P₃ and P₃ purinoceptors in the actions of purines on the contraction of stomach and intestine in *Gasterosteus aculeatus*. Our results show that purinoceptors in the gastrointestinal tract of teleosts are involved not only in regulating muscular contractions but also in the absorption of Ca²⁺.

ATP-stimulated Ca²⁺ influx has been demonstrated in a variety of cell types [1–6]. However, the literature on ATP-stimulated Ca²⁺ uptake in intestinal cells is scarce. Kimmich and Randles [11] found an increase in cytosolic Ca²⁺ concentration in isolated chicken intestinal epithelial cells when 2 mM ATP was added. Chlorpromazine, a calmodulin antagonist, inhibited ATP-stimulated Ca²⁺ uptake in these cells. In cell lines of human colonic epithelial origin, 100 μM ATP increased the cytosolic Ca²⁺ concentration 20-fold over the resting level [10]. An extracellular P₂ purinoceptor, regulating epithelial cell ion transport, was suggested on the basis of the potency of different agonists (ATP > ADP > Nadenosine). Exogenous ATP increased Ca²⁺ uptake 2–6-fold in isolated rat intestinal epithelial cells [9]. A maximal effect was observed at 1 mM ATP. Adenosine, 5'AMP, ADP and non-hydrolysable ATP analogues proved ineffective. However, the slowly hydrolysable ATP analogue ATP[S] fully mimicked the ATP-stimulated Ca²⁺ uptake. The calmodulin antagonist pirenlyamine inhibited the ATP effect, which was also observed by Popper and Batra [3] in a human ovarian cancer cell line. The inhibition by pirenlyamine is congruent with observations on chlorpromazine inhibition [11]. Richards et al. [9] suggest that hydrolysis of a terminal phosphate of ATP is required for the stimulated Ca²⁺ uptake, but they do not rule out the involvement of a nucleotide-specific receptor. To summarize, experimental results on ATP-stimulated Ca²⁺ uptake in (mammalian) enterocytes indicate the involvement of a calmodulin-sensitive P₂ purinoceptor. However, the membrane domain in which this putative purinoceptor resides remains unresolved.

A prerequisite for a functional purinergic receptor in the enterocyte’s brush border membrane is the presence of the proper ligand, i.e. ATP, in the intestinal lumen. One point that needs to be addressed is the source of the ligand. A possible source for luminal ATP would be sloughed-off epithelial cells. In isolated enterocytes from rat and human, cellular values of ATP were measured to range from 5 to 6 nmol of ATP/mg of protein [38]. If we assume cellular ATP levels in tilapia enterocytes to be in the same range, we calculate that a luminal concentration of 0.9 mM ATP is equivalent to 150–180 mg of protein/ml of luminal fluid. Assuming a cytoplasmic ATP concentration of 5 mM [31], cellular dimensions of 5 μm x 5 μm x 20 μm, and a cellular volume of 5 x 10⁻¹⁶ litre for an enterocyte, we calculate that a luminal ATP concentration of 0.9 mM is equivalent to 4 x 10⁴ cells per ml of luminal fluid. We therefore do not think that sloughed-off enterocytes are a plausible source for ATP. Ingested food could be another source for luminal ATP, but the industrially processed fish feed we provide our fish contains no detectable amounts of ATP. Ultrastructural studies on intestinal absorptive cells in tilapia (S. E. Wendelaar Bonga, unpublished work) and other teleost species [39–41] demonstrate the presence of numerous mitochondria and clear vesicles in the apical cytoplasm of the enterocyte. It is tempting to correlate these structural phenomena with the presence of a secretory pathway for ATP in the intestine. Every cell could potentially serve as a source of extracellular ATP [1,31], and nanomolar/micromolar pericellular ATP concentrations have been predicted [1]. These predicted ATP levels differ by at least one order of magnitude from the nucleotide concentrations measured in intestinal luminal samples. The regulation of intestinal transmembrane Ca²⁺ transport by extracellular ATP of enterocytic origin, via a P₂ purinoceptor, is an interesting working hypothesis for future research.
