Head and neck squamous cell carcinoma (HNSCC) is the sixth most common cancer worldwide, and several molecular pathways that underlie the molecular tumorigenesis of HNSCC have been identified. Among them, amplification or overexpression of ΔNp63 isoforms is observed in the majority of HNSCCs. Here, we unveiled a ΔNp63-dependent transcriptional program able to regulate the metabolism and the signaling of hyaluronic acid (HA), the major component of the extracellular matrix (ECM). We found that ΔNp63 is capable of sustaining the production of HA levels in cell culture and in vivo by regulating the expression of the HA synthase HAS3 and two hyaluronidase genes, HYAL-1 and HYAL-3. In addition, ΔNp63 directly regulates the expression of CD44, the major HA cell membrane receptor. By controlling this transcriptional program, ΔNp63 sustains the epithelial growth factor receptor (EGF-R) activation and the expression of ABCC1 multidrug transporter gene, thus contributing to tumor cell proliferation and chemoresistance. Importantly, p63 expression is positively correlated with CD44, HAS3, and ABCC1 expression in squamous cell carcinoma datasets and p63-HA pathway is a negative prognostic factor of HNSCC patient survival. Altogether, our data shed light on a ΔNp63-dependent pathway functionally important to the regulation of HNSCC progression.

HNSCC | p63 | hyaluronic acid

The cross-talk between cells and the components of the extracellular matrix (ECM) is fundamental in multicellular organisms and regulates several biological processes in both physiological and pathological conditions (1). Hyaluronic acid (HA), the major component of the ECM, is a non-sulfated, linear glycosaminoglycan (GAG), which not only contributes to tissue hydration and proper tissue architecture, but also plays important biological functions, including control of cell proliferation, cell motility, cell adhesion, survival, and inflammation (2, 3). These cellular events are mainly mediated by HA binding to specific cell-surface receptors, including CD44, the most common and ubiquitous expressed HA receptor (4). In mammals, HA synthesis occurs on the cellular plasma membrane by means of three hyaluronan synthase isoenzymes (HAS1, HAS2, and HAS3) that extrude the growing HA polymer into the pericellular or the extracellular space (3, 5).

HA synthesis is counteracted by a degradative pathway that clears HA by endocytic uptake and/or HA hydrolysis (6). In humans, there are six hyaluronidase (HYAL) genes (HYAL-1–4, HYAL-P1, and the sperm-specific PH-20). Among them, HYAL-1 and HYAL-2 are the best characterized HYALs and they can have different catalytic properties (7).

Based on its role in important biological processes, it is not surprising that deregulation of HA metabolism and signaling are common events in several pathological conditions such as tumor development (8). Deregulation of HA production during tumor progression is often associated with alterations of the enzymes that regulate HA synthesis and degradation. Overexpression of either HAS2 or HAS3 is associated with higher malignancy or metastasis in several tumor types, such as breast and prostate carcinomas (9, 10). Although these data indicate that deregulation of HA production is tightly linked with tumor progression, our knowledge of the molecular mechanism(s) linking oncogenes and HA metabolism has not yet been elucidated.

p63 is a transcription factor belonging to the p53 family, and it is expressed as distinct protein isoforms (11, 12). ΔNp63 isoforms are the most expressed variants in the basal cells of stratified and glandular epithelia, and its overexpression and/or genomic amplification is observed in up to 80% of squamous cell carcinomas (SCCs) of the head and neck, skin, lung, and esophagus (13). Moreover, several genetic alterations occurring in head and neck squamous cell carcinoma (HNSCC), such as NOTCH1 mutation and ACTL6A amplification, favors p63 transcriptional activity (14, 15). At molecular level, ΔNp63 isoforms, although

Significance

The p63 isoform ΔNp63, a master regulator of epithelial biology, is overexpressed/amplified in the majority of head and neck squamous cell carcinoma (HNSCC), the sixth most common cancer worldwide. Here, we provide a demonstration of a molecular and functional link between the activity of ΔNp63 and hyaluronic acid (HA), a major component of the extracellular matrix. We unveiled a ΔNp63-dependent transcriptional program involving genes regulating the metabolism (HAS3 and HYAL proteins) and the signaling (CD44) of HA. By directly controlling the expression of these HA-related genes, ΔNp63 contributes to the activation of proproliferative and prosurvival pathway in HNSCC. Accordingly, the p63/HA pathway is a negative prognostic factor of HNSCC patient survival.

lacking a canonical transcriptional activation domain, are endowed with an alternative activation domain that enable them to stimulate the expression of several target genes involved in the regulation of stemness, cell migration, invasion, and cell adhesion (16–18). However, ΔNp63 isoforms are also able to repress the transcription of several target genes by different mechanisms (19, 20).

Here, we report evidence demonstrating that ΔNp63 supports HNSCC proliferation and chemoresistance by modulating epithelial growth factor receptor (EGF-R) activation and the expression of the ABC transporter ABCC1 in a HA-dependent manner.

Results

ΔNp63 Regulates the Expression of HA Metabolism Genes. During tumorigenesis, extensive remodeling of the ECM supports and enhances tumor growth. To identify novel p63 target genes potentially regulating ECM in HNSCC, we combined microarray data performed in A253 cell line upon p63 depletion (Supporting Information) with coexpression studies in human primary SCC datasets, searching for ECM-related genes whose expression is linked with that of p63. By cross-analyzing these data, we focused our attention on the HA synthase HAS3 and the hyaluronidase HYAL-1. We found that HAS3 expression is positively correlated with that of TP63 in HNSCC, esophageal carcinoma, and lung squamous cancer datasets (Fig. S1A). Silencing of p63 markedly decreased HAS3 expression in A253, Detroit-562, and FaDu cells (Fig. L4 and Fig. S1B). These HNSCC cell lines mainly express the ΔNp63 isoforms (Fig. S1C), suggesting that these p63 isoforms might regulate HAS3 expression. Accordingly, the specific depletion of ΔNp63 isoforms efficiently decreased HAS3 expression at mRNA and protein levels (Fig. 1B and Fig. S1D). As a complementary approach, we found that the ectopic expression of ΔNp63α in SCC-9 cells, in which endogenous p63 levels are undetectable (Fig. S1E), dramatically increases HAS3 mRNA (Fig. S1F). We also confirm the p63-dependent regulation of HAS3 expression in a xenotransplantation experiment. We inoculated FaDu cells stably expressing a doxycycline-inducible shp63 RNA in nude athymic mice. p63 silencing upon doxycycline treatment markedly decreased the proliferative capacity in vitro (Fig. S2E) and the growth of xenotransplanted tumors (Fig. 1C). Importantly, the expression of HAS3 mRNA is significantly decreased in p63-silenced tumors (Fig. 1D). To further investigate the mechanism of the ΔNp63-dependent regulation of HAS3 expression, we verified whether ΔNp63 is able to bind to the HAS3 locus. To this aim, we performed a ChIP experiment in FaDu cells relying on ChIP-seq data performed on human primary keratinocytes (NHEK) (Fig. S3A). We found that endogenous ΔNp63 is able to occupy a p63-binding site (p63 BS) located in the HAS3 promoter site, at −5 kb from the transcription start site (TSS) (Fig. 1E). Furthermore, exogenous ΔNp63Δr greatly enhanced the HAS3 promoter-mediated luciferase activity (Fig. S3B).

In addition to HAS3, our microarray data revealed that p63 silencing affects HYAL-1 mRNA levels (Supporting Information). In this case, we observed that the expression of HYAL-1 is increased upon p63 silencing at both mRNA and protein levels (Fig. 1F). p63 depletion also increased the mRNA levels of HYAL-3, another member of the hyaluronidases family. Notably, HYAL-1 expression is also augmented in explanted tumors upon p63 silencing (Fig. 1G). HYAL-1 and HYAL-3 genes are clustered together on chromosome 3p21.3, and we found that endogenous ΔNp63 is able to bind to two p63-binding sites, p63 BS#1 and BS#2, located in the HYAL-3 promoter site and in the 3′-end of HYAL-1 gene, respectively (Fig. 1H and Fig. S3C). Altogether, these results indicated that the HA synthase HAS3 and the hyaluronidases HYAL-1 and HYAL-3 are bona fide ΔNp63 transcriptional target genes in vitro and in vivo.

Fig. 1. ΔNp63 directly induces the expression of the HA-related genes. (A) HAS3 and p63 mRNA levels were quantified by qRT-PCR in the indicated HNSCC cancer cell lines transfected with scramble (SCR) or p63 siRNA (si63) oligos. Bars represent the mean of three technical replicates (n = 3; PCR runs) ± SD and are representative of two independent experiments (n = 2 biological replicates). *P < 0.05. (B) Total protein lysates or purified membrane-bound proteins of FaDu cells transfected with SCR, si63, ΔNp63 (siΔp63), or HAS3 siRNA oligos (siHAS3) were subjected to immunoblotting using antibodies to the indicated proteins. (C) FaDu cells stably infected with doxycycline-inducible shp63 expression particles (polyclonal population) were injected into the dorsal flank region of athymic female nude mice (n = 6 per group). The tumor volume growth curves are shown as mean ± SEM on the Left. Images of the explanted tumors are shown on the Right. (D) Total RNA extracted by untreated (shp63 off, n = 6) or doxycycline treated mice (shp63 on, n = 6) was utilized for qRT-PCR analysis of the absolute expression of HAS3 mRNA. **P < 0.01. (E) ChIP analysis of endogenous ΔNp63 occupancy at the p63 binding site of HAS3 locus. (F) HYAL-1, HYAL-2, and HYAL-3 mRNA levels were measured by qRT-PCR (Left) in FaDu cells transfected as in A. Bars represent the mean of three technical replicates (n = 3; PCR runs) ± SD and are representative of two independent experiments (n = 2 biological replicates). *P < 0.05. In parallel, total protein lysates were analyzed by immunoblotting using antibodies to the indicated proteins (Right). (G) HYAL-1 mRNA levels were quantified by qRT-PCR in explanted tumors as described in D. (H) ChIP analysis of endogenous ΔNp63 occupancy at the p63 BS#1 and BS#2 of Hyals loci.

ΔNp63 Controls Hyaluronic Acid Levels. In light of the finding that ΔNp63 is able to transcriptionally regulate genes involved in HA metabolism, we tested whether ΔNp63 was capable of regulating HA levels. The HA polymer is synthesized by the HA synthases and extruded into the pericellular or the extracellular space. We stained pericellular HA by immunofluorescence using the high-affinity HA binding protein HABP, and we found that ΔNp63 depletion decreases the levels of pericellular HA (Fig. S4A). To quantify this effect, we measured HA levels in cell medium by ELISA, and we confirmed that ΔNp63-depleted cells display a marked reduction of HA levels in FaDu and A253 cells (Fig. 2A and Fig. S4B), similarly to the HAS3-silenced cells (Fig. S4C). Conversely, we found that the ectopic expression of ΔNp63α isoform increases HA cellular levels (Fig. 2B). To further validate the correlation between p63 and HA levels, we performed an immunohistochemistry (IHC) staining of p63 and HA in a HNSCC tissue microarray (TMA). We first confirmed the specificity of HABP probe in tumor tissues by pretreating the section with Streptomyces hyaluronidase (Fig. S4D). Although HA can be produced by stromal and tumor cells, we observed a correlation between the expression of p63 and the tumor-associated HA content in 57 tumor samples (Fig. 2C and D). In support of these data, we found that HA tumor-associated levels are markedly decreased in xenograft tumors upon silencing of p63 (Fig. 2E). Collectively, these results indicated that ΔNp63 is able to regulate HA cellular levels, likely via transcriptional regulation of HAS3.

ΔNp63 Directly Induces the Expression of the HA Receptor CD44. CD44 is the most tumor-relevant HA receptor, and de-regulation of the expression of its variant isoforms is associated with advanced diseases and chemoresistance in HNSCC (4, 21). By analyzing coexpression data in esophageal and lung squamous carcinoma datasets, we found that CD44 mRNA expression is positively correlated with that of TP63 (Fig. S5A). To validate these data in human HNSCC tissues, we analyzed p63 and CD44 protein levels by IHC in the HNSCC TMA. We observed a positive correlation between p63 and CD44 expression (Fig. 3A and B). Importantly, gain or loss of function of ΔNp63 expression markedly affected the expression of CD44 at mRNA and protein levels (Fig. 3C and D and Fig. S5 B and C). Conversely, the expression of RHAMM, another well-characterized HA receptor, is not affected by ΔNp63 depletion (Fig. S5D). These transcriptional effects are likely due to a direct binding of ΔNp63 on the CD44 locus. Indeed, by ChIP assay, we demonstrated the ability of endogenous ΔNp63 to bind two p63-binding sites, p63 B5#1 and p63 B5#2 located in the promoter region and in the first intron of CD44 gene, respectively (Fig. 3E and Fig. S5E). All together these results demonstrated that ΔNp63 is able to directly regulate the expression of CD44 by physically recognizing two p63-binding elements located in the CD44 locus.

The ΔNp63-HA Pathway Regulates EGF-R Activation. Since the HA/CD44 interaction promotes the activation of receptor tyrosine kinases (RTKs) (22, 23), we tested whether ΔNp63 is capable of favoring RTKs activation in a HA-dependent manner. By using a RTK signaling antibody array, we found that among several RTKs and signaling nodes, tyrosine phosphorylation of EGF-R and the activation of some downstream effectors, including Akt, ERK1/2, and S6 ribosomal protein, are markedly decreased upon p63 silencing in A253 and FaDu cells (Fig. S6A). We validated these data using two different p63 targeting siRNA oligos, which are both able to reduce EGF-R phosphorylation in several HNSCC cell lines (Fig. 4A and Fig. S6B). In addition to EGF-R phosphorylation, ΔNp63 depletion reduced the phosphorylation of ErbB2, an ErbB family member whose activation is stimulated by the HA/CD44 complex (23).

To investigate whether the ΔNp63-HA pathway might affect the activation of the EGF-R, first we tested the effect of 4-methylumbelliflorone (4-MU), a chemical inhibitor of the enzymatic activity of the HAS synthases (24), on EGF-R phosphorylation. We found that 4-MU treatment markedly reduces the phosphorylation of EGF-R and ErbB2 in A253 and FaDu cells, concomitantly with a decrease of the pericellular HA amount (Fig. 4B and Fig. S6C). Similarly, depletion of HAS3 gene expression by siRNA decreased EGF-R phosphorylation in HNSCC cells (Fig. 4C and Fig. S6D). In a reverse experiment, overexpression of ΔNp63α or HAS3 increased EGF-R phosphorylation (Fig. 4D and Fig. S6E). Importantly, HAS3 inhibition by 4-MU treatment reverted the ability of exogenous ΔNp63 to enhance the activation of EGF-R, Akt, and ERK1/2 (Fig. 4E). Since EGF-R transduction pathway activates proliferative signals, we measured the proliferative capabilities of ΔNp63 or HAS3 silenced cells by a cell counting assay. We found that the siRNA-mediated depletion of HAS3 results in a decrease of cell proliferation (Fig. 4F). All together, these observations indicated that ΔNp63 favors the activation of oncogenic signals of EGF-R by, at least in part, modulating the HA/CD44 pathway.

Fig. 2. ΔNp63 controls HA levels. (A) FaDu cells were transfected with scramble (SCR) or p63 siRNA oligos (sip63). Forty-eight hours after transfection, growth medium of transfected cells was utilized to quantitatively measure the levels of extracellular HA by ELISA assay. HA intracellular levels were normalized against the number of cells (1 × 10⁶). Bars represent the mean of three technical replicates (n = 3) ± SD and are representative of two independent experiments (n = 2 biological replicates). *P < 0.05. (B) SCC-9 cells infected with empty or ΔNp63-expressing lentiviral particles were analyzed as in A. (C) Representative images of IHC analysis of p63 and HA staining in HNSCC tissues. Red boxes indicate higher-magnification images. (D) Correlation plot of p63 and HA H scores in 57 human HNSCC tumor samples including 50 cases of squamous cell carcinoma and 7 adenoid cystic carcinomas. Pearson’s correlation coefficient (r) and the P value of the correlation study are reported. (E) Representative images of IHC analysis of p63 and HA staining in mouse xenograft tumor tissues upon p63 depletion.
ΔNp63/HA Axis Regulates ABC Drug Transporter Expression, and It Is a Negative Prognostic Factor for HNSCC Patient Survival. The HA/CD44 interaction modulates the chemosensitivity of cells to various antineoplastic agents (21). Therefore, we tested whether deregulation of the ΔNp63-HA axis might impact the chemosensitivity of HNSCC cells toward the cytotoxic effect of sublethal doses of doxorubicin and cisplatin. We found that upon chemotherapeutic agent treatment, p63 or HAS3 silencing increases the percentage of apoptotic cells and the cleavage of PARP, an apoptotic marker (Fig. 5B). A similar effect was observed in cells treated with the HAS inhibitor 4-MU (Fig. S7B). As a complementary approach, we tested whether the ectopic expression of ΔNp63 might exert a prosurvival effect in cells exposed to doxorubicin. We found that upon ectopic expression of p63 or HAS3, there is an increase in the expression of ABCB3 transporter was not affected by ΔNp63 or HAS3 depletion (Fig. S7F). Notably, ΔNp63 depletion, similarly to HAS3 depletion, reduced ABC1 mRNA levels in HNSCC cells (Fig. 5C). On the contrary, the expression of ABCB3 transporter was not affected by ΔNp63 or HAS3 depletion (Fig. S7F). In agreement with these data, we found that TP63/ABC1 and HAS3/ABCC1 coexpression is positively correlated in HNSCC dataset as well as in esophageal SCC (Fig. S7G).

Based on these results, we can postulate that the p63/HA axis would act as a negative prognostic factor in patients with HNSCC. We therefore analyzed the overall patient survival of two groups of HNSCC patients: those displaying high p63/HAS3 coexpression and those with low coexpression (Fig. 5D, Lower). We found that patients displaying high p63 and HAS3 coexpression show a decrease of the overall survival compared with those with low expression (Fig. 5D). All together, these findings indicated that p63-HA pathway is a negative

(F) FaDu cells were plated in 6 wells (8 × 10^4 cells per well), and after 24 h, transfected with SCR, siHAS3, or sip63. Six days after transfection, cells were counted by Trypan blue dye exclusion in triplicate. Data are shown as the mean ± SD (n = 3); *, p < 0.05.
locus is observed in the majority of invasive HNSCCs (13, 27). Overexpression and/or amplification of the TP63 locus is observed in the majority of invasive HNSCCs (28). Here, we not only identify an HA-related transcriptional program directly regulated by ΔNp63 in HNSCC, but also provide a demonstration that this program is functionally important to molecularly link ΔNp63 activity with two critical pathways in HNSCC biology: EGF-R signaling and chemoresistence. We demonstrated that ΔNp63 sustains HA signaling by directly regulating the expression of HAS3, HYALs, and CD44 (see proposed model, Fig. 5E). In human tumors, HA is pivotal for various aspects of tumors pathobiology (29, 30), and the biological outcome of tumor-associated HA accumulation vary and likely depends not only on its levels but also on the size of HA polymers (31). Intriguingly, HAS3 synthesizes low molecular weight chains of HA that have been associated with activation of proliferative signals (32). Accordingly, the overexpression of HAS3 in several tumors is associated with higher malignancy (33), and HAS3 knockdown negatively impacts esophageal tumor growth in vivo (34). Although these data identify HAS3 as a regulator of tumor growth, there are no data unveiling the molecular mechanism(s) regulating its expression in tumor cells. Our data unveil that HAS3 expression is under control of the transcription factor ΔNp63.

Regarding the HA catabolic genes, the role of HYAL proteins during tumorogenesis is controversial, acting as tumor promoters or suppressors, likely reflecting the different biological activities exerted by the HA catabolic products. Interestingly, HYAL-2 produces highly angiogenic and protumorigenic HA polymers (35), which are subsequently degraded by HYAL-1 in tetrasaccharides (7). Therefore, it is possible that ΔNp63, by inhibiting the expression of HYAL-1, maintains the high levels of the 20-kDa protumorigenic fragments of HA.

In addition to regulating enzymes involved in the HA metabolism, we also showed that ΔNp63 directly regulates the expression of CD44, the major cell membrane HA receptor. Although several published studies have suggested a potential molecular link between ΔNp63 activity and CD44 in breast cancer (36, 37), our data demonstrate that ΔNp63 directly controls the expression of CD44 in HNSCC and unveil the biological significance of the p63-CD44 axis. We focused our attention on two closely interconnected pathways, which are functionally related to the HNSCC pathobiology: the EGF-R signaling and the regulation of the expression of multidrug transporter genes. EGF-R is overexpressed in more than 90% of HNSCCs, and its expression has been correlated with poor outcome (13). Previous reports suggested that ΔNp63 activity is linked to the deregulation of EGF-R signaling (18, 38). In detail, it has been demonstrated that ΔNp63 transcriptionally induces EGF-R transcription in prostatic cancer cells (38). However, we did not observe any change of the EGF-R protein levels in HNSCC cells upon p63 silencing, suggesting that the ΔNp63-dependent regulation of EGF-R transcription (18, 38) is not confirmed by our data. Conversely, we propose a HA-dependent mechanism, which molecularly links ΔNp63 activity and EGF-R signaling. We found that in HNSCC cells the ΔNp63-dependent effect on EGF-R signaling relies, at least in part, on its ability to regulate HA metabolism. Interestingly, EGF-R expression is positively correlated with that of HAS3 in human esophageal tumors (34) and that the activation of EGF-R led to an induction of HAS3 expression in ovarian and lung tumor cells (39). Therefore, ΔNp63-HAS3 pathway might be sustained by a positive feedback by the EGF-R signaling in HNSCC.

HA-CD44 signaling also promotes resistance to multiple antineoplastic agents, including cisplatin, methotrexate, and doxorubicin (40, 41). We found that the regulation of HA metabolism and signaling mediates, at least in part, the ΔNp63 prosurvival action and reduce the cytotoxic effect of cisplatin and doxorubicin in HNSCC. This effect is likely mediated by the regulation of the expression of the ABCB1 transporter (also known as MRPL1) by the ΔNp63-HA pathway. Elevated ABCB1 expression levels have been detected in many hematopoietic and solid tumors, and a significant statistical association of high ABCB1 protein levels with poor response in prechemotherapy biopsies of esophageal adenocarcinoma patients has been reported (42). However, the molecular mechanisms regulating ABCB1 expression in human tumors are not well known. We found that ΔNp63 or HAS3 depletion decreases the expression of ABCB1. Importantly, both HAS3 and ΔNp63 expression are positively

### Discussion

HNSCCs are characterized by high mortality rate and intrinsic chemoresistence (13, 27). Overexpression and/or amplification of the TP63 locus is observed in the majority of invasive HNSCCs (28). Here, we not only identify an HA-related transcriptional program directly regulated by ΔNp63 in HNSCC, but also provide a demonstration that this program is functionally important to molecularly link ΔNp63 activity with two critical pathways in HNSCC biology: EGF-R signaling and chemoresistence. We demonstrated that ΔNp63 sustains HA signaling by directly regulating the expression of HAS3, HYALs, and CD44 (see proposed model, Fig. 5E). In human tumors, HA is pivotal for various aspects of tumors pathobiology (29, 30), and the biological outcome of tumor-associated HA accumulation vary and likely depends not only on its levels but also on the size of HA polymers (31). Intriguingly, HAS3 synthesizes low molecular weight chains of HA that have been associated with activation of proliferative signals (32). Accordingly, the overexpression of HAS3 in several tumors is associated with higher malignancy (33), and HAS3 knockdown negatively impacts esophageal tumor growth in vivo (34). Although these data identify HAS3 as a regulator of tumor growth, there are no data unveiling the molecular mechanism(s) regulating its expression in tumor cells. Our data unveil that HAS3 expression is under control of the transcription factor ΔNp63.

Regarding the HA catabolic genes, the role of HYAL proteins during tumorogenesis is controversial, acting as tumor promoters or suppressors, likely reflecting the different biological activities exerted by the HA catabolic products. Interestingly, HYAL-2 produces highly angiogenic and protumorigenic HA polymers (35), which are subsequently degraded by HYAL-1 in tetrasaccharides (7). Therefore, it is possible that ΔNp63, by inhibiting the expression of HYAL-1, maintains the high levels of the 20-kDa protumorigenic fragments of HA.

In addition to regulating enzymes involved in the HA metabolism, we also showed that ΔNp63 directly regulates the expression of CD44, the major cell membrane HA receptor. Although several published studies have suggested a potential molecular link between ΔNp63 activity and CD44 in breast cancer (36, 37), our data demonstrate that ΔNp63 directly controls the expression of CD44 in HNSCC and unveil the biological significance of the p63-CD44 axis. We focused our attention on two closely interconnected pathways, which are functionally related to the HNSCC pathobiology: the EGF-R signaling and the regulation of the expression of multidrug transporter genes. EGF-R is overexpressed in more than 90% of HNSCCs, and its expression has been correlated with poor outcome (13). Previous reports suggested that ΔNp63 activity is linked to the deregulation of EGF-R signaling (18, 38). In detail, it has been demonstrated that ΔNp63 transcriptionally induces EGF-R transcription in prostatic cancer cells (38). However, we did not observe any change of the EGF-R protein levels in HNSCC cells upon p63 silencing, suggesting that the ΔNp63-dependent regulation of EGF-R transcription (18, 38) is not confirmed by our data. Conversely, we propose a HA-dependent mechanism, which molecularly links ΔNp63 activity and EGF-R signaling. We found that in HNSCC cells the ΔNp63-dependent effect on EGF-R signaling relies, at least in part, on its ability to regulate HA metabolism. Interestingly, EGF-R expression is positively correlated with that of HAS3 in human esophageal tumors (34) and that the activation of EGF-R led to an induction of HAS3 expression in ovarian and lung tumor cells (39). Therefore, ΔNp63-HAS3 pathway might be sustained by a positive feedback by the EGF-R signaling in HNSCC.

HA-CD44 signaling also promotes resistance to multiple antineoplastic agents, including cisplatin, methotrexate, and doxorubicin (40, 41). We found that the regulation of HA metabolism and signaling mediates, at least in part, the ΔNp63 prosurvival action and reduce the cytotoxic effect of cisplatin and doxorubicin in HNSCC. This effect is likely mediated by the regulation of the expression of the ABCB1 transporter (also known as MRPL1) by the ΔNp63-HA pathway. Elevated ABCB1 expression levels have been detected in many hematopoietic and solid tumors, and a significant statistical association of high ABCB1 protein levels with poor response in prechemotherapy biopsies of esophageal adenocarcinoma patients has been reported (42). However, the molecular mechanisms regulating ABCB1 expression in human tumors are not well known. We found that ΔNp63 or HAS3 depletion decreases the expression of ABCB1. Importantly, both HAS3 and ΔNp63 expression are positively

### Fig. 5. ΔNp63-HA pathway regulates HNSCC chemoresistence, and it is a negative prognostic factor of HNSCC patient survival. (A) FaDu cells transfected with scramble (SCR), p63 (sip63), or HAS3 siRNA oligos (siHAS3) were treated with doxorubicin (0.4 μM) for 48 h. Cells were then stained with propidium iodide (PI) and fluorodacetate (FDA), and the percentage of apoptotic cells was determined by FACS (Left). Data are shown as the mean ± SD of three biological replicates (n = 3). **P < 0.01. In parallel, lysates obtained from treated cells were immunoblotted for the indicated proteins (Right). (B) SCC-9 cells were lentivirally infected with empty or ΔNp63-expressing particles. Forty-eight hours after infection, cells were concomitantly treated with doxorubicin (0.4 μM) and 4-MU (0.3 mM) for 48 h, and then cell viability was measured by Celltiter-Glo. Data are shown as the mean ± SD of three technical replicates (n = 3). **P < 0.05. (C) A253 cells were transfected with SCR, sip63, or siHAS3, and 48 h after transfection, ABC1 mRNA levels were measured by qRT-PCR. Data are shown as the mean ± SD of three technical replicates (n = 3, PCR runs) and are representative of two independent experiments (n = 2 biological replicates). **P < 0.05. (D) Patient samples from the TCGA cohort were clustered into two groups displaying low and high TP63 and HAS3 expression, respectively, and analyzed for survival (P value: 0.0068). Clustered expression values relative to mean expression are shown in the heat map Pearson’s correlation coefficient (PCC): 0.5959, P value: 9.9639e-51. (E) Schematic model of the ΔNp63-mediated regulation of the HA metabolism and signaling.
correlated with ABC11 expression levels in human HNSCC primary tumors. Although we cannot rule out that the prosurvival effect of ΔNp63 can be due to additional pathways, including the HA-dependent modulation of EGF-R signaling proposed here, our data established the existence of a functional connection between ΔNp63 activity, HA metabolism, and drug fluxes that can enhance the intrinsic chemoresistance of HNSCC. Alteration of this circuit would impinge on the capacity of tumor cells to respond to chemotherapy and, therefore, should impact the survival rate of HNSCC patients. Accordingly, we found that in HNSCC patients, the p63-HAS3 axis is a negative prognostic factor of patient survival and it might be thus functionally important to regulate tumor progression.

Materials and Methods

Human HNSCC Tumor Tissues. HNSCC TMA was purchased by US Biomax, Inc (HNB02a). TMA slide includes 61 cases of squamous cell carcinoma, 7 adenoid cystic carcinoma, 1 each of adenocarcinoma and mucoepidermoid carcinoma, plus 10 normal tissues. Score of each tumor samples was calculated as described in detail in Supporting Information. HNSCC tissue sample shown in Fig. 5A4D has been utilized under approval by the institutional review board of University Hospital “Policlinico Tor Vergata” with prior patient consent.

23. Castelli F, et al. (2010) PLENTI-HA-ΔNp63α vector and I. Amelio for assistance in gene microarray analysis. This work has been supported by the My First AIRC (Italian Association for Cancer Research) Grant MIAF-15523 (to A.P.), Medical Research Council Grant IG/15563 (to G.R.), Project FA;BeBi di Qualità, and a CNR grant from the Italian Ministry of Economy and Finance (to G.R.).

ACKNOWLEDGMENTS. We thank F. Bernassola for kindly providing the pLENTI-HA-ΔNp63α vector and I. Amelio for assistance in gene microarray analysis. This work has been supported by the My First AIRC (Italian Association for Cancer Research) Grant MIAF-15523 (to A.P.), Medical Research Council Grant IG/15563 (to G.R.).
