Funding information
The TOPIC trial was funded by The Netherlands Organisation for Health Research and Development grant number 94507606 and the participating institutes. No separate funding was received for this study.

Summary

Background: Leucopenia is a common side effect in patients treated with thiopurines. Variants in the thiopurine S-methyltransferase (TPMT) gene are the best-known risk factor, but only explain up to 25% of leucopenia cases.

Aim: To identify the clinical risk factors for thiopurine-induced leucopenia in patients without a common TPMT variant, and explore if these patients are at increased risk for infections.

Methods: Post hoc analysis of the Thiopurine response Optimisation by Pharmacogenetic testing in Inflammatory bowel disease Clinics (TOPIC) trial. For this analysis, patients without a variant in TPMT (*2, *3A or *3C) were included. Uni- and multivariate Cox-proportional hazard models were used to identify risk factors for leucopenia and infections. Leucopenia was defined as a white blood cell (WBC) count <3.0 × 10^9/L and infections were classified according to the Common Terminology Criteria for Adverse Events.

Results: Sixty hundred and ninety-five patients (90.6%) included in the TOPIC-trial had no variant in TPMT, of which 45 (6.5%) developed leucopenia. Median time to leucopenia was 56 (29-112) days. Multivariate analysis showed that use of mercaptopurine compared to azathioprine was associated with leucopenia (hazard ratio [HR] 2.61 [95% CIs, 1.39-4.88; \( P < .01 \)]) and a higher baseline WBC count was protective (HR 0.80 [95% CIs, 0.71-0.89; \( P < .01 \)]). Risk factors for infections were older age (per 10 year; HR 2.07 [95% CIs, 1.18-3.63; \( P = .01 \)]) and concomitant use of biologic drugs (HR 2.15 [95% CIs, 1.14-4.07; \( P = .02 \)].

Conclusions: Low baseline WBC count and mercaptopurine, due to a relatively higher dose, were risk factors for thiopurine-induced leucopenia in patients without a TPMT variant.
1 | INTRODUCTION

Thiopurines are immunosuppressive drugs that have an important role in the treatment of inflammatory bowel diseases (IBD), both as monotherapy and as combination treatment with biologics.1-3 Yet many patients have to discontinue treatment in an early phase due to ineffectiveness or side effects. Leucopenia as a result of thiopurine use is a frequent reason for dose reductions and/or (temporary) treatment discontinuation in patients with IBD, leading to suboptimal treatment conditions.4,5 Dose reductions or treatment discontinuation in case of leucopenia is mainly driven by fear for infectious complications.4

The best-known risk factor for the development of thiopurine-induced leucopenia is the presence of genetic variants in the thiopurine S-methyltransferase (TPMT) gene, which leads to a reduced or negligible TPMT enzyme activity and subsequently to excessive cytotoxic 6-thioguanine nucleotide (6-TGN) metabolite formation.6,7 In the Caucasian population, 95% of the decreased TPMT enzyme activity follows from three common variants (TPMT*2, TPMT*3A or TPMT*3C).7 Especially patients with a homozygous genetic variant in TPMT (~0.3% of the population), and to a lesser degree patients with a heterozygous variant in TPMT (~10% of the population) are at increased risk for severe, life-threatening, myelosuppression when treated with the standard recommended dose of azathioprine (AZA) or mercaptopurine (MP).8-10 Leucopenia can be prevented by genotyping for these variants prior to initiation of thiopurine treatment and subsequently taper the thiopurine dose to 50% of the original dose in those heterozygous for a variant in TPMT and 0%-10% of the original dose in patients with a homozygous variant.11-13 However, only up to 25% of the leucopenia cases can be explained by variants in TPMT, which makes that leucopenia is frequently observed in patients without a TPMT variant.5,14-16 This suggests that also other genes and environmental or clinical factors may contribute to the risk of leucopenia during thiopurine treatment.17-21

It is unknown to what degree leucopenia attributes to the risk for infections. Recent studies in the treatment of hepatitis C did not reveal a relation between interferon-induced leucopenia and infectious complications.22,23 If this also applies for thiopurine treatment in IBD, strict dose reductions in case of leucopenia might be redundant.

In the present post hoc analysis of the “Thiopurine response Optimisation by Pharmacogenetic testing in Inflammatory bowel disease Clinics” (TOPIC) trial, we aimed to (1) identify clinical risk factors for the development of TPMT-independent leucopenia in patients with IBD treated with thiopurines and (2) evaluate whether TPMT-independent leucopenia is a risk factor for the occurrence of infections in these patients.

2 | METHODS

2.1 | Patients

We designed a case-control study with patient data from the TOPIC trial, which evaluated the efficacy of pre-treatment TPMT genotyping on the occurrence of myelosuppression during thiopurine treatment.24 In brief, in the TOPIC trial thiopurine-naive patients with IBD with an indication for thiopurine treatment (indicated by the treating physician) were randomised 1:1 for the intervention group with prior to treatment genotyping of the three most common genetic variants (*2, *3A and *3C) in TPMT vs the standard of care group with thiopurine dosing according to current standard of care; AZA (2.0-2.5 mg/kg) and MP (1.0-1.5 mg/kg). In patients allocated to the intervention arm, a 50% dose reduction was recommended in case of a heterozygous TPMT variant and in case of a homozygous TPMT variant 10% of the standard dose or an alternative treatment was advised. Patients were followed for 20 ± 6 weeks with laboratory measurements including white blood cell (WBC) count at week 0, 1, 2, 4, 6, 8, 20 and when indicated by the treating physician.

Neutrophil count was not routinely measured in the TOPIC trial. Physicians were free in their choice for AZA or MP and were advised to start full dose. After the follow-up period, TPMT-genotype was assessed in patients randomised to the standard of care arm and in addition TPMT activity was assessed in all patients. Main exclusion criteria of the TOPIC trial were previous use of thiopurines, co-treatment with allopurinol, baseline WBC count <3.0 x 10^9/L, baseline liver test abnormalities (alanine transaminase, aspartate transaminase, alkaline phosphatase and/or gamma glutamate transpeptidase ≥ two times the normal upper limit), known TPMT enzyme activity or TPMT-genotype. 6-Methylmercaptopurine ribonucleotides (6-MMPR) and 6-TGN levels were assessed at week eight in the first 301 patients included in the trial. For a detailed description of the study design, patient selection and patient data, we refer to Coenen et al14 The TOPIC trial was approved by the institutional ethics committee and all patients provided written informed consent (clinicaltrials.gov, NCT00521950).

The primary aim of the current study was to indentify risk factors for leucopenia in patients without one of the tested genetic variants in TPMT. All randomised patients who started with a thiopurine and tested negative for a variant in TPMT were included in an intention-to-treat analysis (Figure 1). Patients allocated to the genotyping arm with a TPMT variant (treated with 50% of the regular dose), as well as patients assigned to the standard of care arm with a TPMT variant (treated with 100% of the regular dose) were excluded. The Common Terminology Criteria for Adverse Events (CTCAE) version 4.0 was used to classify the severity of leucopenia.24 According to these criteria, mild leucopenia (grade 1) is defined as a WBC count between the lower limit of normal and ≥3.0 x 10^9/L, moderate leucopenia (grade 2) was defined as a WBC count between ≥2.0 x 10^9/L and <3.0 x 10^9/L and severe leucopenia (grade 3) if the WBC count was <2.0 x 10^9/L. For the current analysis, only cases of moderate and severe leucopenia were included. Leucopenia which developed 2 weeks or later after discontinuation of the thiopurine was not considered to be associated with thiopurine use.

The second goal of this study was to explore if patients with TPMT-independent leucopenia during thiopurine treatment were at increased risk for infections. For this analysis, infections were classified according to the CTCAE.24 The source of infection was reported
and severity was subdivided in grade 1-5, in which grade 1 means no indication for infection treatment, grade 2: oral intervention (antibiotics, antifungal or anti-viral) treatment indicated, grade 3: intravenous treatment (antibiotics, antifungal or anti-viral) or operative intervention indicated, grade 4: life-threatening consequences and grade 5 indicates death from the infection. Only clinical relevant infections, grade 2 or higher, were included in the analysis, ie, infections for which oral or intravenous antibiotic, antifungal or anti-viral treatment was indicated. Infections up to 2 weeks after thiopurine treatment discontinuation were included. Infections were classified as ‘leucopenia-associated infection’ when the infection occurred while the patient was leucopenic (WBC count <3.0 \times 10^9/L) or within 2 weeks after the leucopenia was resolved.

Covariates included in the analysis were baseline (week 0) WBC count and week one decrease in WBC count, defined as the decrease in WBC level after 7 (±1) days of thiopurine use. Furthermore, use of concomitant drugs, ie, use of 5-aminosalicylic acid (5-ASA), steroids, biologics and ACE-inhibitors at baseline or initiated during the use of the initial thiopurine was reported. Steroids with limited systemic bioavailability, such as budesonide were not included. Information about co-morbidities (diabetes mellitus, chronic pulmonary disease and rheumatoid diseases) was reported. Patients were classified as active smoker or nonsmoker, determined at baseline. Disease severity at baseline was classified according to the Harvey-Bradshaw Index in patients with Crohn’s disease (CD) and partial Mayo score for ulcerative colitis (UC). AZA dose in mg/kg was divided by 2.08 for comparison with MP dose.12,25

2.2 | TPMT enzyme activity and TPMT genotyping

TPMT enzyme activity was measured in red blood cells (RBCs) using a high-performance liquid chromatography method described previously.14 Genotyping of variants ‘2, ‘3A and ‘3C in TPMT was described previously.14 Possible cases of TPMT-induced leucopenia caused by rare variants, other than ‘2, ‘3A and ‘3C in TPMT, might have been missed. For this reason, we sequenced all exons including splice sites in the TPMT gene in patients with a low TPMT activity (<60 mg 6-methylguanine/mmolHb.h) or who developed leucopenia (WBC <3.0 \times 10^9/L). Polymerase chain reaction was performed on 10 ng DNA using AmpliTaq Gold 360 mastermix (Life Technologies, Bleiswijk, The Netherlands). Primers are described elsewhere.14 Annealing temperature was 56°C for all exons. PCR products were purified using Multiscreen filter plates (Millipore Carrigtwohill, Cork, Ireland). Purified products were used for Sanger sequence analysis (bidirectional) with dye-termination chemistry (BigDye Terminator, version 3) on a 3730 DNA analyser (Applied Biosystems, Inc., Foster City, CA, USA.

2.3 | 6-MMPR and 6-TGN metabolite measurements

By protocol, 6-TGN and 6-MMPR levels at week eight were assessed at a routine check-up in the first 301 patients included in the TOPIC trial. 6-TGN and 6-MMPR levels were determined in RBCs by high-performance liquid chromatography according to the Lennard method.14 Median (IQR) thiopurine metabolite concentrations are presented in pmol/8x10^9RBCs.
2.4 Statistical analysis

All analyses were performed using SPSS version 20.0.0.1 (SPSS Inc., Chicago, IL, USA). First, leucopenia rate was calculated for patients without one of the tested TPMT variants. Characteristics of patients with and without TPMT-independent leucopenia were compared by Chi-squared test (categorical data) or independent t test (continuous data). Nonparametric tests were used when data were not distributed normally. In a similar fashion, characteristics of patients with and without an infection during the use of the initial thiopurine were analysed. In patients with steady-state metabolite levels at week 8, the 6-MMPR, the 6-TGN levels and the 6-MMPR/6-TGN ratio were compared by Mann-Whitney U test in patients with and without TPMT-independent leucopenia.

Univariate Cox-proportional hazard models were used to identify clinical factors associated with the development of leucopenia in patients without one of the tested TPMT variants. The time to leucopenia and in patients without leucopenia the number of days of thiopurine use served as reference. Variables with a \( P < .2 \) were included in a multivariate Cox-proportional hazard model with backward elimination to explore which factors were independently associated with the development of TPMT-independent leucopenia during thiopurine treatment. In the same way, uni- and multivariate Cox-proportional analysis was performed to identify factors associated with the occurrence of infections during thiopurine treatment. The variable leucopenia was retained in this model, since we wanted to explore whether these patients were at increased risk for infections. A \( P < .05 \) was considered as statistically significant.

3 RESULTS

3.1 Patients

Of the 796 patients with IBD randomised in the TOPIC trial, 29 patients were excluded because they did not start with a thiopurine or were lost to follow-up. Of the remaining 767 patients who actually started with thiopurine treatment, 72 (9.4%) carried a genetic variant in TPMT and were excluded, which leaves 695 patients with IBD for this analysis (Figure 1). Of the 695 included patients, 247 patients (35.5%) were treated with MP (mean dose 1.20 ± 0.20 mg/kg) and 448 patients (64.5%) were treated with AZA (mean dose ± SD 2.19 ± 0.20 mg/kg). To compare the AZA dose with the MP dose, a conversion rate of 2.08 was applied, resulting in a mean converted dose of 1.05 ± 0.09 mg/kg. T test showed that the difference was significant (\( P < .001 \)).

3.2 Leucopenia

Of the 695 patients without a variant in TPMT, 45 (6.5%) developed leucopenia in the first 5 months of treatment; 41 (5.9%) patients developed moderate leucopenia and four (0.6%) patients developed severe leucopenia. See Table S1 for detailed information of the 45 patients with TPMT-independent leucopenia. Median time (IQR) to onset of leucopenia was 56 (29-112) days. In 11 patients (24.4%) with TPMT-independent leucopenia the thiopurine treatment was discontinued, while in 20 patients (44.5%) the thiopurine dose was reduced, in 12 patients (26.7%) leucopenia recovered without an intervention and in two patients (4.4%) the intervention was unknown. TPMT enzyme activity mean (±SD) was not different between patients with and without leucopenia (95.8 ± 21.8 vs 94.4 ± 18.8 mg/mmol Hb.h, \( P = .65 \); Figure 2).

Table 1 shows the characteristics of patients with and without TPMT-independent leucopenia during thiopurine treatment. Table 2 provides the results of the uni- and multivariate Cox-proportional hazard model and shows that the choice for MP compared to AZA, Hazard ratio (HR) 2.61 (95% CIs 1.39-4.88; \( P < .01 \)) was an independent risk factor for TPMT-independent thiopurine-induced leucopenia. Furthermore, a higher baseline WBC count protected the patient from TPMT-independent thiopurine-induced leucopenia, HR 0.80 (95% CIs 0.71-0.89; \( P < .01 \)) for every increase of WBC at baseline with 1.0 \( \times 10^9/L \) the risk of leucopenia decreased with 0.80.

In 17 patients who developed leucopenia after 8 weeks, steady-state 6-MMPR and 6-TGN levels were assessed. Neither 6-TGN levels, nor 6-MMPR levels, nor the 6-MMPR/6-TGN ratio were different from patients without leucopenia in whom steady-state week eight levels were assessed: 267 (205-364) pmol/8 \( \times 10^8 \) RBCs vs 242 (186-341) pmol/8 \( \times 10^8 \) RBCs, \( P = .39 \) and 3596 (1304-12 824) pmol/8\( \times 10^8 \) RBCs vs 3600 (1326-7 415) pmol/8 \( \times 10^8 \) RBCs, \( P = .63 \). The 6-MMPR/6-TGN median (IQR) ratio was 13 (6-35) in patients with leucopenia and 14 (6-32) in patients without leucopenia, \( P = .80 \).

3.3 Infections

Sixty-five (9.4%) of the 695 patients developed an infection while being treated with a thiopurine during the study period of 5 months.
infections were classified as grade 2 or higher was 54 (18-88) days. Of the 45 patients with TPMT-independent leucopenia five patients (11.1%), of whom three had a severe leucopenia (WBC count <2.0 x 10^9/L), experienced a "leucopenia-associated infection", while the infection rate in patients without leucopenia was 54 in 650 patients (8.3%) (P = .41). Details about infection localisations are depicted in Table 3. Characteristics of patients with and without an infection are presented in Table 4. In the multivariate Cox-proportional hazard model only age (per 10 years), HR 2.07 (95% CI, 1.18-3.63; P = .01) and concomitant use of biologic drugs, HR 2.15 (95% CI, 1.14-4.07; P = .02), were associated with the occurrence of infections (Table 5).

4 | DISCUSSION

In this study, we showed that in patients with IBD without a variant in TPMT, baseline WBC count and the choice of MP compared to AZA, were independent risk factors for thiopurine-induced leucopenia during the first five months of treatment. However, this did not result in a higher risk for infections. Infections during thiopurine treatment were more frequently seen in elderly and in patients with concomitant use of biologic drugs.

The overall incidence of thiopurine-induced leucopenia is estimated to be 7%. Importantly, in 75% of the patients this is not correlated with a genetic variant in TPMT. As shown in this study, leucopenia still occurs in 6.5% of the patients without a genetic variant in TPMT, often leading to dose reductions or treatment discontinuation. Thiopurine-induced leucopenia is at least partially dose-dependent. In a previous analysis of all patients included in the TOPIC trial, we already showed that patients treated with MP were relatively higher dosed than patients treated with AZA and that this resulted in amongst others a higher rate of leucopenia. This difference annulled in a secondary analysis with adjustment for dose and metabolite levels, therefore an interdrug difference between AZA and MP seems unlikely. Also, other studies showed a relatively higher dose and leucopenia rate in patients on MP compared to AZA. The difference might be attributed to the absence of MP tablets with a content of 25 mg, which allow a more personalised dosing. Another explanation might be derived from the conversion rate of 2.08, which is used to calculate the MP dose from the AZA dose. This conversion rate includes assumptions such as a 100% bioavailability. The higher rate of dose-dependent side effects might be prevented with a slight reduction of the MP starting dose.

In our study, 6-TGN and 6-MMPR metabolite levels were not increased in patients with leucopenia. It must be stressed that most patients with leucopenia were subjected to dose reductions or treatment discontinuation before week eight. Therefore, steady-state week eight 6-TGN levels were available only in a limited number of cases, which most likely explains why we found no difference. Besides 6-TGN levels, also excessively elevated 6-MMPR levels have been associated with leucopenia. The increased risk for leucopenia with a lower baseline WBC count has also been reported in the

Leucopenia was defined as a white blood cell count (WBC) of <3.0 x 10^9/L. AZA, azathioprine; BMI, body mass index; CD, Crohn’s disease; HBI; Harvey-Bradshaw Index; TPMT, thiopurine S-methyltransferase; UC, ulcerative colitis; WBC, white blood cell.  
AZA dose in mg/kg was divided by 2.08 to compare with MP dosage.  
Seven patients were diagnosed with indeterminate colitis.  
Known for 492 patients.  
Known for 602 patients.  
Known for 325 patients with CD.  
Known for 225 patients with UC.

Fifty-nine (8.5%) infections were classified as grade 2 or higher according to the CTCAE, of these, 32 patients had a grade 2 infection, 25 patients a grade 3 infection and 2 patients were classified as grade 4 infection. Two patients died during the TOPIC trial, both were excluded from this analysis, one patient had a heterozygous TPMT variant and the other patient developed an infection while he was treated with steroids, infliximab and methotrexate, more than 2 weeks after thiopurine treatment was discontinued. Median (IQR) time after the start of thiopurine treatment to an infection grade 2 or higher was 54 (18-88) days. Of the 45 patients with TPMT-independent leucopenia five patients (11.1%), of whom three had a severe leucopenia (WBC count <2.0 x 10^9/L), experienced a "leucopenia-associated infection", while the infection rate in patients without leucopenia was 54 in 650 patients (8.3%) (P = .41). Details about infection localisations are depicted in Table 3. Characteristics of patients with and without an infection are presented in Table 4. In the multivariate Cox-proportional hazard model only age (per 10 years), HR 2.07 (95% CI, 1.18-3.63; P = .01) and concomitant use of biologic drugs, HR 2.15 (95% CI, 1.14-4.07; P = .02), were associated with the occurrence of infections (Table 5).
myelosuppression. Previous studies using data of the TOPIC trial of the TPMT enzyme activity and therefore may increase the risk of concomitant 5-ASA use and myelosuppression. It has been suggested that 5-ASA might increase 6-TGN levels by a weak inhibition of the TPMT enzyme activity and therefore may increase the risk of myelosuppression. Previous studies using data of the TOPIC trial already showed that 6-TGN levels were not significantly higher in patients on 5-ASA, which explains why we found no increased leucopenia rate in this group. It is known that smoking leads to –independent leucopenia. In the present study, we showed that infection rates are comparable for patients with and without TPMT-related leucopenia and infections might have great implications for clinical practice. Some studies showed a relation between mild leucopenia and infections increases with neutrophil levels below 0.5 × 10^9/L. Yet thiopurine dosage was reduced or treatment was discontinued in two-thirds of these patients, probably due to fear for infectious complications. Overall, most cases of TPMT-independent leucopenia are mild and therefore did not require immediate treatment discontinuation or dose reduction. However in the setting of an unknown TPMT-genotype, all cases of leucopenia in the first months of thiopurine treatment should be considered as potentially TPMT-induced, because otherwise life-threatening myelosuppression might occur in the patients whom actually have a genetic variant in TPMT. Previous studies estimated a cumulative infection rate of 6.5% among patients with thiopurine-induced leucopenia. In the present study, we showed that infection rates are comparable for patients with and without TPMT-independent leucopenia. Both viral and bacterial infections were seen, however in most of the cases no specific pathogen was isolated. The risk for bacterial infections increases with neutrophil levels below 0.5 × 10^9/L. Yet thiopurine dosage was reduced or treatment was discontinued. It cannot be excluded that this prevented the aggravation of the leucopenia and/or the development of infectious complications, which is an important limitation of our study. Yet, our findings corroborate studies exploring the risk of infections in hepatitis C treatment. In these studies, interferon-induced leucopenia was not a risk factor for infectious complications. The lack of association between leucopenia and infections might have great implications for clinical practice. Some studies showed a relation between mild leucopenia (defined as WBC count ≥2.0 × 10^9/L) and treatment efficacy. This increased treatment efficacy in case of leucopenia remained mandatory to identify patients with myelosuppression in an early stage. In more than 90% of the cases leucocyte levels did not drop below 2.0 × 10^9/L. Yet thiopurine dosage was reduced or treatment was discontinued in two-thirds of these patients, probably due to fear for infectious complications. Overall, most cases of TPMT-independent leucopenia are mild and therefore did not require immediate treatment discontinuation or dose reduction. However in the setting of an unknown TPMT-genotype, all cases of leucopenia in the first months of thiopurine treatment should be considered as potentially TPMT-induced, because otherwise life-threatening myelosuppression might occur in the patients whom actually have a genetic variant in TPMT. Previous studies estimated a cumulative infection rate of 6.5% among patients with thiopurine-induced leucopenia. In the present study, we showed that infection rates are comparable for patients with and without TPMT-independent leucopenia. Both viral and bacterial infections were seen, however in most of the cases no specific pathogen was isolated. The risk for bacterial infections increases with neutrophil levels below 0.5 × 10^9/L. A 5-TGN level of 6 to 7 nmol/L was observed in only one patient, which suggests that severe neutropenia is not frequently observed in patients without a TPMT variant. This, in combination with the fact that in most cases leucopenia was only moderate (WBC count ≥50% of the patients and a neutrophil count below 0.5 × 10^9/L) might explain why we did not find a higher infection rate in patients with a thiopurine-induced leucopenia. It must be mentioned that in 69% of patients with leucopenia the thiopurine dose was reduced or treatment was discontinued. It cannot be excluded that this prevented the aggravation of the leucopenia and/or the development of infectious complications, which is an important limitation of our study. Yet, our findings corroborate studies exploring the risk of infections in hepatitis C treatment. In these studies, interferon-induced leucopenia was not a risk factor for infectious complications. The lack of association between leucopenia and infections might have great implications for clinical practice. Some studies showed a relation between mild leucopenia (defined as WBC count ≥3.0 and <5.0 × 10^9/L) and treatment efficacy. This increased treatment efficacy in case of leucopenia remained mandatory to identify patients with myelosuppression in an early stage. In more than 90% of the cases leucocyte levels did not drop below 2.0 × 10^9/L. Yet thiopurine dosage was reduced or treatment was discontinued in two-thirds of these patients, probably due to fear for infectious complications. Overall, most cases of TPMT-independent leucopenia are mild and therefore did not require immediate treatment discontinuation or dose reduction. However in the setting of an unknown TPMT-genotype, all cases of leucopenia in the first months of thiopurine treatment should be considered as potentially TPMT-induced, because otherwise life-threatening myelosuppression might occur in the patients whom actually have a genetic variant in TPMT. Previous studies estimated a cumulative infection rate of 6.5% among patients with thiopurine-induced leucopenia. In the present study, we showed that infection rates are comparable for patients with and without TPMT-independent leucopenia. Both viral and bacterial infections were seen, however in most of the cases no specific pathogen was isolated. The risk for bacterial infections increases with neutrophil levels below 0.5 × 10^9/L.
was independent from 6-TGN levels. Therefore, if our observations are correct, a more preserved strategy in case of moderate leucopenia would not increase infection risk, prevents a patient from underdosing, and possibly increases treatment efficacy. Future studies are needed to evaluate whether such a strategy is safe and does increase the infection rate or lead to more patients with severe leucopenia.

Age and concomitant use of biologics were the only factors associated with the occurrence of infections. Increasing age is a known risk factor for infections, which is thought to result from an impaired immune response in the elderly. This has also been reported in patients with IBD. In contrast to many clinical trials, there was no upper age limit with inclusion in the TOPIC trial. As a consequence, 105 (15.1%) of the patients included in current study were 60 years or older, of whom 24 patients were 70 years or older. This makes it a representative sample for the real life setting in the era of an ageing IBD population. The higher risk for infections with concomitant use of biologic drugs is not unexpected, since use of biologics is an independent risk factor for (opportunistic) infections. This observation is not limited to IBD, but is also observed in other immune-mediated diseases. In contrast to previous studies, we found no relation with concomitant steroid use. A likely explanation is that steroid use was not protocolised and as a consequence the group of patients on oral steroids was very heterozygous and

Leucopenia was defined as a WBC count of <3.0 × 10⁹/L. Only infections grade 2 or higher according to the Common Terminology Criteria for Adverse Events were included.

AZA, azathioprine; BMI, body mass index; CD, Crohn’s disease; HBI; Harvey-Bradshaw Index; TPMT, thiopurine S-methyltransferase; UC, ulcerative colitis; WBC, white blood cell.

aAZA dose in mg/kg was divided by 2.08 to compare with MP dosage.
bSeven patients were diagnosed with indeterminate colitis.
cknown for 492 patients.
dKnown for 602 patients.
eKnown for 325 patients with CD.
fKnown for 225 patients with UC.
gAs follows from Table 3, 45 patients experienced leucopenia, however in 3 patients with leucopenia during thiopurine treatment who also had an infection, the infection was not considered to be related to leucopenia, either because leucopenia was already resolved for more than 2 weeks (2 patients), or the infection was already known before the leucopenia occurred (1 patient). For the analysis, these cases were counted as an infection without leucopenia.
Finally, (viral) infections may induce leucopenia. 19 This comes with some restrictions, since exacerbations of IBD or flu-like side effects (which might include elevation of C-reactive protein) can mimic (gastro-intestinal) infections leading to the prescription of anti-infectious therapy there was a true suspicion of an infection. Furthermore, we assumed that when the treating physician started treatment, patients with a low TPMT activity or those who developed leucopenia; which did not reveal other variants (unpublished data). was circumvented by sequencing the coding region of TPMT in all patients with a low TPMT activity or those who developed leucopenia; which did not reveal other variants (unpublished data). This comes with some restrictions, since exacerbations of IBD or flu-like side effects (which might include elevation of C-reactive protein) can mimic (gastro-intestinal) infections leading to the prescription of antibiotics. Finally, (viral) infections may induce leucopenia. 19 However, if this is the case it would have resulted in an overestimation of ‘leucopenia-associated infections’ and further bolster our findings that (moderate) leucopenia itself is not a risk factor for infectious complications.

In conclusion, in the present study we showed that the choice for MP compared to AZA (as a result of a relatively higher dose) and baseline WBC count are risk factors for the development of thiopurine-induced leucopenia in patients without a genetic variant in TPMT; however, this was not associated with an increased risk for infections. Multivariate analysis showed that older patients and patients with concomitant use of biologics had a higher risk for infections during thiopurine treatment and should therefore be treated with more caution. Our data suggest that moderate TPMT-independent leucopenia during thiopurine treatment might be accepted in the light of close monitoring of WBC count and metabolite levels.

Infections were classified according to the Common Terminology Criteria for Adverse Events 4.0 (version 4.0). Only infections grade 2 or higher were included. WBC, white blood cell.

In conclusion, in the present study we showed that the choice for MP compared to AZA (as a result of a relatively higher dose) and baseline WBC count are risk factors for the development of thiopurine-induced leucopenia in patients without a genetic variant in TPMT; however, this was not associated with an increased risk for infections. Multivariate analysis showed that older patients and patients with concomitant use of biologics had a higher risk for infections during thiopurine treatment and should therefore be treated with more caution. Our data suggest that moderate TPMT-independent leucopenia during thiopurine treatment might be accepted in the light of close monitoring of WBC count and metabolite levels.

ACKNOWLEDGEMENT

We thank the patients for participation in the study. We thank Rene H.M. te Morsche and Wilbert H.M. Peters from the Department of Gastroenterology, Radboud University Medical Center, Nijmegen, The Netherlands, for the measurement of TPMT activity. Furthermore, we thank Mariëlle Maas, Miet Fiddelaars, Milevis Reitsma, Leonie Peters and Jean Clisson from the department of Clinical Pharmacy and Toxicology, Zuyderyder Medical Center, Sittard-Geleen, The Netherlands for technical assistance with metabolite measurement and Debbie Heinen, Marjolein M.J. van Donkelaar, Freshteh Golestani, Marlies E. de Vos, J.G. Angelien M. Heister, Démérique M.W. Nijsten, Mascha M.V.A.P. Schijvenaars, and Martine E.C. Crakan from the department of Human Genetics, Radboud University Medical Center, Nijmegen, The Netherlands for their support in data-management. We thank Dr. Sita H. Vermeulen, department for Health Evidence, Radboud Institute for Health Sciences, Radboud University Medical Center, Nijmegen, The Netherlands, and Professor Barbara Franke, department of Human Genetics, Donders Institute for Brain, Cognition and Behaviour, Radboud University Medical Center, Nijmegen, The Netherlands, for their contribution to the design of the TOPIC trial. At last, we thank Professor Joost P.H. Drenth from the Department of Gastroenterology, Radboud University Medical Center, Nijmegen, The Netherlands, for intellectual contribution to the content of the manuscript.

The TOPIC recruitment team was responsible for patient recruitment and collection of clinical data. Compensation was given to the members of the recruitment team for additional biochemical measurements and examinations that had to be performed for the TOPIC study. TOPIC recruitment team members are: Department of Gastroenterology, Academisch Ziekenhuis Maastricht, Maastricht, The Netherlands—AAM Mascleee, MD; PhD, M Pierik, MD, PhD; W Mares, MD; W Hameeteman, MD, PhD; Department of Gastroenterology, Rijnstate Ziekenhuis Arnhem, Arnhem, The Netherlands—PJ Wahab, MD; PhD, H Seinen, MD, PhD; Department of Gastroenterology, Amphia Ziekenhuis, Breda, The Netherlands—MCM Rijk, MD, PhD; IM Harkema, MD, PhD; Department of Gastroenterology, Atrium Medisch Centrum, Heerlen, The Netherlands—M de Bièvre, MD; L Oostenbrug, MD, PhD; CM Bakker, MD,
AUTHORSHIP

Guarantor of the article: M.M.T.J. Broekman.

Author contributions: All authors listed were involved in the study design and interpretation of data for the work. All authors had access to the data and have approved the final version of the manuscript for publication. MB, MC responsibility for the integrity of the data and accuracy of the data analysis. CM, MC, DJ collected data. Metabolite measurements were performed under guidance of DW and PH. Data analysis was performed by MB, MC, DJ, GW, DW with input from the other investigators. The manuscript was written by MB, MC, DJ, GW and all other authors edited the manuscript and gave final approval for publication. MB, MC had full access to all the data in the study and take responsibility for the integrity of the data and the accuracy of the data analysis.
