Abstract

Test generation and execution are often hampered by the large state spaces of the systems involved. In automata (or transition system) based test algorithms, taking advantage of symmetry in the behavior of specification and implementation may substantially reduce the amount of tests. We present a framework for describing and exploiting symmetries in black box test derivation methods based on finite state machines (FSMs). An algorithm is presented that, for a given symmetry relation on the traces of an FSM, computes a subautomaton that characterizes the FSM up to symmetry. This machinery is applied to Chow’s classical W-method for test derivation. Finally, we focus on symmetries defined in terms of repeating patterns.

1 Introduction

It has long been recognized that for the proper functioning of components in open and distributed systems, these components have to be thoroughly tested for interoperability and conformance to internationally agreed standards. For thorough and efficient testing, a high degree of automation of the test process is crucial. Unfortunately, methods for automated test generation and execution are still seriously hampered by the often very large state spaces of the implementations under test. One of the ways to deal with this problem is to exploit
structural properties of the implementation under test that can be safely assumed to hold. In this paper we focus on taking advantage of symmetry that is present in the structure of systems. The symmetry, as it is defined here, may be found in any type of parameterized system: such parameters may for example range over IDs of components, ports, or the contents of messages.

We will work in the setting of test theory based on finite state machines (FSMs). Thus, we assume that the specification of an implementation under test is given as an FSM and the implementation itself is given as a black box. From the explicitly given specification automaton a collection of tests is derived that can be applied to the black box. Exploiting symmetry will allow us to restrict the test process to subautomata of specification and implementation that characterize these systems up to symmetry and will often be much smaller. The symmetry is defined in terms of an equivalence relation over the trace sets of specification and implementation. Some requirements are imposed to ensure that such a symmetry indeed allows to find the desired subautomata. We instantiate this general framework by focusing on symmetries defined in terms of repeating patterns. Some experiments with pattern-based symmetries, supported by a prototype tool implemented using the Open/CÆSAR tool set [14], have shown that substantial savings may be obtained in the number of tests.

Since we assume that the black box system has some symmetrical structure (cf. the uniformity hypothesis in [15, 6]), it is perhaps more appropriate to speak of gray box testing. For the specification FSM it will generally be possible to verify that a particular relation is a symmetry on the system, but for the black box implementation one has to assume that this is the case. The reliability of this assumption is the tester’s responsibility. In this respect, one may think of exploiting symmetry as a structured way of test case selection [13, 4] for systems too large to be tested exhaustively, where at least some subautomata are tested thoroughly.

This paper is not the first to deal with symmetry in protocol testing. In [21], similar techniques have been developed for a test generation methodology based on labeled transition systems, success trees and canonical testers [3, 25]. Like in our case, symmetry is an equivalence relation between traces, and representatives of the equivalence classes are used for test generation. Since our approach and the approach in [21] start from different testing methodologies, it is not easy to compare them. In [21], the symmetry relation is defined through bijective renamings of action labels; our pattern-based definition generalizes this approach. On the other hand, since in our case a symmetry relation has to result in subautomata of specification and implementation that characterize these systems up to the symmetry, we have to impose certain requirements, which are absent in [21].

In [19], symmetrical structures in the product automaton of interoperating systems are studied. It is assumed that the systems have already been tested in isolation and attention is focused on pruning the product automaton by exploiting symmetry arising from the presence of identical peers. In the present paper, we abstract away from the internal composition of the system and focus on defining a general framework for describing and using symmetries on FSMs.

This paper is organized as follows. Section 2 contains some basic definitions concerning FSMs and their behavior. In Section 3, we introduce and define a general notion of trace based symmetry. We show how, given such a symmetry on the behavior of a system, a subautomaton of the system can be computed, a so-called kernel, that characterizes the behavior of the system up to symmetry. In Section 5 we apply the machinery to Chow’s classical W-method.
for test derivation. In Section 6 we will instantiate the general framework by focusing on symmetries defined in terms of repeating patterns. Section 7 contains an extensive example, inspired by [24]. Finally, we discuss future work in Section 8.

2 Finite state machines

In this section, we will briefly present some terminology concerning finite state machines and their behavior, that we will need in the rest of this paper.

We let \( \mathbb{N} \) denote the set of natural numbers. (Finite) Sequences are denoted by greek letters. Concatenation of sequences is denoted by juxtaposition; \( \epsilon \) denotes the empty sequence and the sequence containing a single element \( a \) is simply denoted \( a \). If \( a \) is non-empty then \( \text{first}(a) \) returns the first element of \( a \) and \( \text{last}(a) \) returns the last element of \( a \).

If \( V \) and \( W \) are sets of sequences and \( \sigma \) is a sequence, then \( \sigma W = \{ \sigma \tau \mid \tau \in W \} \) and \( V W = \bigcup_{\sigma \in V} \sigma W \). For \( X \) a set of symbols, we define \( X^0 = \{ \epsilon \} \) and, for \( i > 0 \), \( X^i = X^{i-1} \cup X^i \). As usual, \( X^* = \bigcup_{i \in \mathbb{N}} X^i \).

Definition 2.1. A finite state machine (FSM) is a structure \( A = (S, \Sigma, E, s^0) \) where

- \( S \) is a finite set of states
- \( \Sigma \) a finite set of actions
- \( E \subseteq S \times \Sigma \times S \) is a finite set of edges
- \( s^0 \in S \) is the initial state

We require that \( A \) is deterministic, i.e., for every pair of edges \( (s, a, s'), (s, a', s'') \) in \( E_A \), \( s' = s'' \).

We write \( S_A, \Sigma_A, \) etc., for the components of an FSM \( A \), but often omit subscripts when they are clear from the context. We let \( s, s' \) range over states, \( a, a', b, c, \ldots \) over actions, and \( e, e' \) over edges. If \( e = (s, a, s') \) then \( \text{act}(e) = a \). We write \( s \xrightarrow{a} s' \) if \( (s, a, s') \in E \) and with \( s \xrightarrow{a} \) we denote that \( s \xrightarrow{a} s' \) for some state \( s' \). A subautomaton of an FSM \( A \) is an FSM \( B \) such that \( s_B^0 = s_A^0 \), \( S_B \subseteq S_A \), \( \Sigma_B \subseteq \Sigma_A \), and \( E_B \subseteq E_A \).

An execution fragment of an FSM \( A \) is an alternating sequence \( \gamma = s_0 a_1 s_1 \cdots a_n s_n \) of states and actions of \( A \), beginning and ending with a state, such that for all \( i \), \( 0 \leq i < n \), we have \( s_i \xrightarrow{a_{i+1}} s_{i+1} \). If \( s_0 = s_n \) then \( \gamma \) is a loop, if \( n \neq 0 \) then \( \gamma \) is a non-empty loop. An execution of \( A \) is an execution fragment that begins with the initial state of \( A \).

For \( \gamma = s_0 a_1 s_1 \cdots a_n s_n \) an execution fragment of \( A \), \( \text{trace}(\gamma) \) is defined as the sequence \( a_1 a_2 \cdots a_n \). If \( \sigma \) is a sequence of actions, then we write \( s \xrightarrow{\sigma} s' \) if \( A \) has an execution fragment \( \gamma \) with \( \text{first}(\gamma) = s \), \( \text{last}(\gamma) = s' \), and \( \text{trace}(\gamma) = \sigma \). If \( \gamma \) is a loop, then \( \sigma \) is a looping trace. We write \( s \xrightarrow{\sigma} \) if there exists an \( s' \) such that \( s \xrightarrow{\sigma} s' \), and write \( \text{traces}(s) \) for the set \( \{ \sigma \in (\Sigma_A)^* \mid s \xrightarrow{\sigma} \} \). We write \( \text{traces}(A) \) for \( \text{traces}(s_A^0) \). □

3
3 Symmetry

In this section we introduce the notion of symmetry employed in this paper.

We want to be able to restrict the test process to subautomata of specification and implementation that characterize these systems up to symmetry. In papers on exploiting symmetry in model checking [2, 8, 10, 11, 12, 18], such subautomata are constructed for explicitly given FSMs by identifying and collapsing symmetrical states. We are concerned with black box testing, and, by definition, it is impossible to refer directly to the states of a black box. In traditional FSM based test theory, FSMs are assumed to be deterministic and hence a state of a black box is identified as the unique state of the black box that is reached after a certain trace of the system. Thus it seems natural to define symmetry as a relation over traces.

Our basic notion of symmetry on an FSM $A$, then, is an equivalence relation on $(\Sigma_\mathcal{A})^\ast$, such that $A$ is closed under the symmetry, i.e., if a sequence of actions is symmetrical to a trace of $A$ then the sequence is a trace of $A$ too.

The idea is to construct from the specification automaton an automaton such that its trace set is included in the trace set of the specification and contains a representative trace for each equivalence class of the symmetry relation on the traces of the specification. In order to be able to do this, we need to impose some requirements on the symmetry. For the specification we demand (1) that each equivalence class of the symmetry is represented by a unique trace, (2) that prefixes of a trace are represented by prefixes of the representing trace, and (3) that representative traces respect loops. The third requirement means that if a representative trace is a looping trace, then the trace with the looping part removed is also a representative trace. This requirement introduces some state-based information in the definition of symmetry.

These requirements enable us to construct a subautomaton of the specification, a so-called kernel, such that every trace of the specification is represented by a trace from the kernel. Of course, it will often be the case that the symmetry itself is preserved under prefixes and respects loops, so the requirements will come almost for free.

For the black box implementation, we will, w.r.t. symmetry, only demand that it is closed under symmetry. So if tests have established that the implementation displays certain behavior, then by assumption it will also display the symmetrical behavior. In Section 5, where the theory is applied to Mealy machines, we will in addition need a way to identify a subautomaton of the implementation that is being covered by the tests derived from the kernel of the specification.

**Definition 3.1.** A symmetry $S$ on an FSM $\mathcal{A}$ is pair $(\simeq, (\cdot)\rangle$ where $\simeq$ is a binary equivalence relation on $(\Sigma_\mathcal{A})^\ast$, and $(\cdot)\rangle : (\Sigma_\mathcal{A})^\ast \to (\Sigma_\mathcal{A})^\ast$ is a representative function for $\simeq$ such that:

1. $\mathcal{A}$ is closed under $\simeq$: If $\sigma \in \text{traces}(\mathcal{A})$ and $\sigma \simeq \tau$, then $\tau \in \text{traces}(\mathcal{A})$.

2. Only traces of the same length are related: If $\sigma \simeq \tau$, then $|\sigma| = |\tau|$.

3. $(\cdot)\rangle$ satisfies:

   (a) $\sigma^{r} \simeq \sigma$

   (b) $\tau \simeq \sigma \Rightarrow \tau^{r} = \sigma^{r}$
(c) \( ()^r \) is prefix closed on \( \mathcal{A} \): If \( \sigma a \in \text{traces}(\mathcal{A}) \) and \( (\sigma a)^r = \tau b \), then \( \sigma^r = \tau \).

(d) \( ()^r \) is loop respecting on representative traces: If \( (\sigma_1 \sigma_2 \sigma_3)^r = \sigma_1 \sigma_2 \sigma_3 \in \text{traces}(\mathcal{A}) \) and \( \sigma_2 \) is a looping trace, then \( (\sigma_1 \sigma_3)^r = \sigma_1 \sigma_3 \).

The class of traces \( \tau \) such that \( \tau \simeq \sigma \) is denoted with \([\sigma]_S\), or, if \( S \) is clear from the context, \([\sigma]\).

As mentioned above, we will demand that there exists a symmetry on the specification, while the implementation under test is required only to be closed under the symmetry.

**Lemma 3.2.** \( (\sigma^r)^r = \sigma^r \)

**Definition 3.3.** Let \( S = (\simeq, ()^r) \) be a symmetry on FSM \( \mathcal{A} \). A *kernel* of \( \mathcal{A} \) w.r.t. \( S \) is a subautomaton \( \mathcal{K} \) of \( \mathcal{A} \), such that for every \( \sigma \in \text{traces}(\mathcal{A}) \), \( \sigma^r \in \text{traces}(\mathcal{K}) \).

## 4 Construction of a kernel

In this section, we fix an FSM \( \mathcal{A} \) and a symmetry \( S = (\simeq, ()^r) \) on \( \mathcal{A} \). Figure 1 presents an algorithm that constructs a kernel of \( \mathcal{A} \) w.r.t. \( S \). It basically explores the state space of \( \mathcal{A} \), while keeping in mind the trace that leads to the currently visited state. As soon as such a trace contains a loop, the algorithm will not explore it any further.

In Figure 1, \( \text{enabled}(s, \mathcal{A}) \) denotes the set of actions \( a \) such that \( E \) contains an edge \((s,a,s')\), and for such an \( a \), \( \text{eff}(s,a,\mathcal{A}) \) denotes \( s' \). Furthermore, \( \text{repr}(\sigma,E) \) denotes the set \( F \) of actions such that \( a \in F \) iff there exists an action \( b \in E \) such that \( \sigma^r a = (\sigma b)^r \). We will only call this function for \( \sigma \) such that \( \sigma^r = \sigma \) (see Lemma 4.3). By definition of \( ()^r \), for some action \( c \), \( (\sigma b)^r = \sigma^r c = \sigma c \). So, since \( \mathcal{A} \) is deterministic and closed under \( \simeq \), \( F \subseteq E \) and if \( E \) is non-empty, \( F \) is non-empty. This justifies the function \( \text{choose}(F) \) which nondeterministically chooses an element from \( F \).

The remainder of this section is devoted to the correctness of algorithm Kernel. In order to prove that the algorithm works properly, we first prove that it terminates, that it creates a subautomaton of \( \mathcal{A} \) and that \( \text{build\_it} \) uses its parameters properly.

**Lemma 4.1.** The execution of the algorithm Kernel\((\mathcal{A},S)\) terminates.

**Proof.** The number of states in \( \mathcal{A} \) is finite, and for each nested call of \( \text{build\_it}(s',\sigma',\text{Seen}') \) within \( \text{build\_it}(s,\sigma,\text{Seen}) \), \( \text{Seen}' = \text{Seen} \cup \{s'\} \) with \( s' \not\in \text{Seen} \). So there can be finitely many levels of such nested calls. Furthermore, the number of enabled transitions in \( s \) is finite, so the while loop that empties \( E \) (\( E \) decreases strictly monotonically during this loop until it’s empty) can make finitely many nested calls to \( \text{build\_it} \).

**Lemma 4.2.** During execution of \( \text{build\_it}(s_0,\epsilon,\emptyset) \), automaton \( \mathcal{K} \) is a subautomaton of \( \mathcal{A} \), and \( \mathcal{K} \) grows monotonically.
function Kernel($A$, $S$): FSM;
    var $K$;
    procedure Build_It($s$, $\sigma$, Seen);
    var $a$, $b$, $s$, $s'$, $E$, $F$;
    begin
        if $s \notin$ Seen
        then $E :=$ enabled($s$, $A$);
            $F := \emptyset$;
            while $E \neq \emptyset$
                do $a :=$ choose(repr($\sigma$, $E$));
                    $s' :=$ eff($s$, $a$, $A$);
                    $S_K := S_K \cup \{s'\}$;
                    $\Sigma_K := \Sigma_K \cup \{a\}$;
                    $E_K := E_K \cup \{(s, a, s')\}$;
                    Build_It($s'$, $\sigma a$, Seen $\cup \{s\}$);
                    $F := F \cup \{a\}$;
                    $E := E \setminus \{a\}$;
                    for each $b \in E . \sigma a \simeq \sigma b$
                        do $E := E \setminus \{b\}$;
                            od;
                    od;
        fi;
    end;
begin
    $s_K^0 := s_A^0$;
    $S_K := \{s_A^0\}$;
    $\Sigma_K := \emptyset$;
    $E_K := \emptyset$;
    Build_It($s_A^0$, $\epsilon$, $\emptyset$);
    return $K$;
end.

Figure 1: The algorithm Kernel
Lemma 4.3. If $\text{Kernel}(A,S)$ calls \texttt{build.Jt}(s,\sigma,\text{Seen}) then $s_{K}^{0} \xrightarrow{\sigma \in K} s$ and $\sigma^r = \sigma$.

Proof. By induction on the length $n$ of $\sigma$.

- $n = 0$. Then $\sigma = \epsilon$. From observing the algorithm Kernel and procedure \texttt{build.Jt}, it is clear that the only call of \texttt{build.Jt}(s,\epsilon,\text{Seen}) is with $s = s_{A}^{0}$ and $\text{Seen} = \emptyset$. At this point in $\text{Kernel}(A,S)$, $s_{A}^{0}$ has just been added to $K$ as $s_{K}^{0}$. So $s_{K}^{0} \xrightarrow{\epsilon} \emptyset s$. Certainly, $(\epsilon)^{r} = \epsilon$.

- $n = m + 1$. Suppose $\sigma = \sigma' a$ is a trace of length $m + 1$ and $\text{Kernel}(A,S)$ calls \texttt{build.Jt}(s,\sigma,\text{Seen}). Since $\sigma \neq \epsilon$, the call \texttt{build.Jt}(s,\sigma,\text{Seen}) must occur within the execution of a call \texttt{build.Jt}(s',\sigma',\text{Seen'})'. By the induction hypothesis, we know that $s_{K}^{0} \xrightarrow{\sigma'} \emptyset s'$. When \texttt{build.Jt}(s',\sigma',\text{Seen'}) calls \texttt{build.Jt}(s,\sigma' a,\text{Seen}) with $\sigma'$ then $(s',\sigma,a,s)$ has just been added to $E_{K}$, with $a$ from $\text{enabled}(s,A)$ and $s = \text{eff}(s',a,A)$. So $s' \xrightarrow{a} \emptyset s$ when the call \texttt{build.Jt}(s,\sigma,\text{Seen}) is made, and it follows that $\sigma \in \text{traces}(K)$.

As to $\sigma' = \sigma$. When \texttt{build.Jt}(s',\sigma',\text{Seen'}) calls \texttt{build.Jt}(s,\sigma' a,\text{Seen}) then by definition of \texttt{choose}(repr($\sigma'$,$E$)), $(\sigma')^{r} a = (\sigma' a)^{r}$. Since, by induction hypothesis, $(\sigma')^{r} = \sigma'$, $(\sigma' a)^{r} = \sigma' a$, which completes the proof.

Lemma 4.4. If $\text{Kernel}(A,S)$ calls \texttt{build.Jt}(s,\sigma,\text{Seen}) then $\sigma \in \text{traces}(\text{Kernel}(A,S))$.

Proof. Follows immediately from Lemmas 4.2 and 4.3.

Lemma 4.5. If $\text{Kernel}(A,S)$ calls \texttt{build.Jt}(s,\sigma,\text{Seen}), then during the execution of \texttt{build.Jt} the following holds:

1. during and after the while loop, the following property holds:

   $$a \in F \Rightarrow \text{Kernel}(A,S) \text{ calls } \texttt{build.Jt}(\text{eff}(s,a,K),\sigma a,\text{Seen} \cup \{s\})$$

2. during and after the while loop, the following property holds:

   $$s \xrightarrow{a} \Rightarrow a \in E \lor \exists b \in F, \sigma b = (\sigma a)^{r}$$

3. after the while loop, $E$ is empty.

Proof.

1. When the while loop is started, $F$ is empty. The only statement that adds $b$ to $F$ follows right after the statements that first add the edge $(s,a,s')$ to $E_{K}$ and then call \texttt{build.Jt}(s',\sigma a,\text{Seen} \cup \{s\})$. 

7
2. Suppose $a \notin E$. At the start of the while loop, $E$ contains each enabled action in $s$, including $a$. So $a$ has been removed from $E$ by one of the last two statements of the while loop. In case $a$ was removed from $E$ by the first of these two statements, then it was added to $F$ one statement earlier, and, by definition of $\text{choose}(\text{repr} (\sigma, E))$ and Lemma 4.3, $\sigma a = (\sigma a)^r$. In case $a$ was removed from $E$ by the last of the two statements, then, for $a' = \text{repr} (\sigma, E)$ and Lemma 4.3, $(\sigma a)^r = \sigma a'$.

3. Trivial, since it is the stop condition for the while loop, and the while loop is the last statement in the procedure.

Lemma 4.6. Suppose $\text{Kernel}(A, S)$ calls $\text{buildJt}(s, \sigma, \text{Seen})$ with $\sigma = a_1 a_2 \ldots a_n$, $s_0 \overset{a_1}{\rightarrow}_A s_1 \overset{a_2}{\rightarrow}_A s_2 \ldots \overset{a_n}{\rightarrow}_A s_n$, and $s_0 = s^0_A$. Then

1. $\text{Kernel}(A, S)$ calls $\text{buildJt}(s_0, \epsilon, \emptyset)$

2. for $0 \leq i < n$, $\text{buildJt}(s_i, \sigma_i, \text{Seen}_i)$ calls $\text{buildJt}(s_{i+1}, \sigma_{i+1}, \text{Seen}_{i+1})$ with $\sigma_i = a_1 a_2 \ldots a_i$ and for $0 \leq i < n$, $\text{Seen}_i = \bigcup_{j \in \{0, 1, \ldots, i-1\}} \{s_j\}$

3. $s = s_n$ and $\text{Seen} = \text{Seen}_n$

Proof. By induction on the length $n$ of $\sigma$.

- $n = 0$. Then $\sigma = \epsilon$, and the result follows immediately.

- $n = m + 1$.
  Suppose $\sigma = a_1 a_2 \ldots a_{m+1}$ and $\text{Kernel}(A, S)$ calls $\text{buildJt}(s, \sigma, \text{Seen})$ with $s_0 \overset{a_1}{\rightarrow}_A s_1 \overset{a_2}{\rightarrow}_A s_2 \ldots \overset{a_{m+1}}{\rightarrow}_A s_{m+1}$ and $s_0 = s^0_A$. Let $\sigma' = a_1 a_2 \ldots a_m$. Since $\sigma \neq \epsilon$, the call $\text{buildJt}(s, \sigma, \text{Seen})$ must occur within the execution of a call $\text{buildJt}(s', \sigma', \text{Seen}')$ and $\text{Seen} = \text{Seen}' \cup \{s'\}$. By the induction hypothesis, we know that $\text{Seen}' = \text{Seen}_m$, that $s' = s_m$, that $\text{Kernel}(A, S)$ calls $\text{buildJt}(s_0, \epsilon, \emptyset)$, that for $0 \leq i < m$, $\text{buildJt}(s_i, \sigma_i, \text{Seen}_i)$ calls $\text{buildJt}(s_{i+1}, \sigma_{i+1}, \text{Seen}_{i+1})$ with $\sigma_i = a_1 a_2 \ldots a_i$ and that for $0 \leq i < m$, $\text{Seen}_i = \bigcup_{j \in \{0, 1, \ldots, i-1\}} \{s_j\}$.
  So $\text{buildJt}(s_m, \sigma_m, \text{Seen}_m)$ calls $\text{buildJt}(s_{m+1}, \sigma_{m+1}, \text{Seen})$, and we need to prove that $s = s_{m+1}$ and $\text{Seen}_{m+1} = \text{Seen} = \bigcup_{j \in \{0, 1, \ldots, m\}} \{s_j\}$. Looking at the statements in $\text{buildJt}(s_m, \sigma_m, \text{Seen}_m)$ that call $\text{buildJt}(s_{m+1}, \sigma_{m+1}, \text{Seen})$, we see that $s = s_{m+1}$ and $\text{Seen} = \text{Seen}_m \cup \{s_m\}$. So $\text{Seen} = (\bigcup_{j \in \{0, 1, \ldots, m-1\}} \{s_j\}) \cup \{s_m\} = \bigcup_{j \in \{0, 1, \ldots, m\}} \{s_j\}$ and the result follows.

Lemma 4.7. If $\text{Kernel}(A, S)$ calls $\text{buildJt}(s, \sigma, \text{Seen})$, then

$$s \in \text{Seen} \iff \exists \sigma_1, \sigma_2. \sigma = \sigma_1 \sigma_2 \land \sigma_2 \neq \epsilon \land s^0_A \overset{\sigma_1}{\rightarrow}_A s \overset{\sigma_2}{\rightarrow}_A s$$

Proof. Follows immediately from Lemma 4.6 and Lemma 4.4.
The next theorem completes the proof of the fact that the algorithm $\text{Kernel}(\mathcal{A}, S)$ returns a kernel for $\mathcal{A}$ w.r.t. $S$.

**Theorem 4.8.** Let $\mathcal{K} = \text{Kernel}(\mathcal{A}, S)$. If $\sigma \in \text{traces}(\mathcal{A})$, then $\sigma' \in \text{traces}(\mathcal{K})$.

**Proof.** Let $\tau = \sigma'$. Since $\mathcal{A}$ is closed under $S$, $\tau \in \text{traces}(\mathcal{A})$; say that $s^0_\mathcal{A} \xrightarrow{\tau} \mathcal{A} t$. We prove a stronger property $\text{Inv}(\tau)$ by induction on the length $n$ of $\sigma$ (= the length of $\tau$).

$\text{Inv}(\tau) \equiv \forall \tau \in \text{traces}(\mathcal{K}) \left( \exists \text{Kernel}(\mathcal{A}, S) \text{ calls } \text{build}_\mathcal{K}(i, \tau, \text{Seen}) \land \tau = \tau_1 \tau_2 a \tau_3 \land s^0_\mathcal{A} \xrightarrow{\tau_1} \mathcal{A} t' \xrightarrow{\tau_2} \mathcal{A} t' \xrightarrow{\tau_3} \mathcal{A} t \land \tau_1 \tau_2 \text{ contains no non-empty looping trace in } \mathcal{A} \right)$

- $n = 0$.

Then $\sigma = e$, and also $\tau = e$. So $t = s^0_\mathcal{A}$. Since $s^0_\mathcal{A} \in S_K$, $e \in \text{traces}(\mathcal{K})$. It suffices to observe that $\text{Kernel}(\mathcal{A}, S)$ calls $\text{build}_\mathcal{K}(s^0_\mathcal{A} : e, \varnothing)$.

- $n = m + 1$.

Induction Hypothesis (IH): $0 \leq |\rho| \leq m \Rightarrow \text{Inv}(\rho^p)$

Suppose $\sigma = \sigma' b$, $\tau = \tau' c$, and $|\sigma| = |\tau| = m + 1$. Since $()^{\tau}$ is prefixed closed, $(\sigma')^{\tau} = \tau'$.

Since $\tau \in \text{traces}(\mathcal{A})$, $\tau' \in \text{traces}(\mathcal{A})$. We distinguish two cases.

- $\tau'$ does not contain a non-empty looping trace.

We show that, for some set $\text{Seen}$, $\text{Kernel}(\mathcal{A}, S)$ calls $\text{build}_\mathcal{K}(t, \tau', c, \text{Seen})$. By Lemma 4.4 we then know that $\tau' \in \text{traces}(\mathcal{K})$, which proves $\text{Inv}(\tau)$.

Assume $s^0_\mathcal{A} \xrightarrow{\tau'} \mathcal{A} t'$. Since $(\sigma')^{\tau} = \tau'$, $\text{Inv}(\tau')$ holds by IH. There is no looping trace in $\tau'$, so $\tau' \in \text{traces}(\mathcal{K})$ and, for some set $\text{Seen'}$, $\text{Kernel}(\mathcal{A}, S)$ calls $\text{build}_\mathcal{K}(t', \tau', c, \text{Seen'})$. We now inspect the execution of procedure $\text{build}_\mathcal{K}$ for this call. By Lemma 4.7, we know that $t' \notin \text{Seen'}$. By Lemma 4.5 we know that after the while loop $\text{build}_\mathcal{K}(t''', \tau' c', \text{Seen'} \cup \{t''\})$ is called, for some state $t''$ and action $c'$ such that $t' \xrightarrow{c'} \mathcal{K} t''$ and $(\tau' c')^{\tau'} = \tau' c'$. By Lemma 3.2, we know that $(\tau' c')^{\tau'} = \tau' c'$, so $c' = c$ and hence $t'' = t$. Thus, $\text{build}_\mathcal{K}(t, \tau' c, \text{Seen'} \cup \{t''\})$ is called.

- $\tau'$ contains a non-empty looping trace.

Then there exist $\tau_1, \tau_2, \tau_3, \sigma_1, \sigma_2, \sigma_3, a$, and $t'$ such that

$\tau = \tau_1 \tau_2 a \tau_3 c \land \sigma = \sigma_1 \sigma_2 \sigma_3$

$\tau_1 = |\sigma_1| \land |\tau_2 a| = |\sigma_2| \land |\tau_3 c| = |\sigma_3|$

$s^0_\mathcal{A} \xrightarrow{\tau_1} \mathcal{A} t' \xrightarrow{\tau_2} \mathcal{A} t' \xrightarrow{\tau_3} \mathcal{A} t$

$\tau_1 \tau_2$ contains no non-empty looping trace in $\mathcal{A}$

We show that, for some set $\text{Seen}$, $\text{Kernel}(\mathcal{A}, S)$ calls $\text{build}_\mathcal{K}(t', \tau_1 \tau_2 a, \text{Seen})$, and that $\tau \in \text{traces}(\mathcal{K})$. Trivially, $|\tau_1 \tau_2 a| < |\tau_1 \tau_2 a \tau_3 c|$, and $|\tau_1 \tau_3 c| < |\tau_1 \tau_2 a \tau_3 c|$. 

9
Since \( (*) \) is prefix closed and \( \tau^r = \tau \), \( \tau_1 \tau_2 a = (\tau_1 \tau_2 a)^r \). Since \( (*) \) is loop respecting, \( \tau_1 \tau_3 c = (\tau_1 \tau_3 c)^r \). So we may apply IH and obtain that \( \text{Inv}(\tau_1 \tau_2 a) \) and \( \text{Inv}(\tau_1 \tau_3 c) \) hold. This means that \( \tau_1 \tau_2 a \in \text{traces}(K) \), \( \tau_1 \tau_3 c \in \text{traces}(K) \), and since there is no looping trace in \( \tau_1 \tau_2 \), that, for some set \( \text{Seen} \), \( \text{Kernel}(A, S) \) calls build it \( (t', \tau_1 \tau_2 a, \text{Seen}) \). Since \( K \) is a subautomaton of \( A \) (Lemma 4.2), we know that \( s^0_{K} \xrightarrow{\tau_1} K \xrightarrow{\tau_2 a} K \xrightarrow{t'} K \xrightarrow{\tau_3 c} t \), and hence \( \tau_1 \tau_2 a \tau_3 c \in \text{traces}(K) \).

\[ \Box \]

5 Test derivation from symmetric Mealy machines

In this section we will apply the machinery developed in the previous sections to Mealy machines. There exists a wealth of test generation algorithms based on the Mealy machine model [1, 5, 7]. We will show how Chow’s classical W-method [7] can be adapted to a setting with symmetry. The main idea is that test derivation is not based on the entire specification automaton, but only on a kernel of it. A technical detail here is that we do not require Mealy machines to be minimal (as already observed by [20] for the setting without symmetry).

**Definition 5.1.** A Mealy machine is a (deterministic) FSM \( A \) such that

\[ \Sigma_A = \{(i/o) \mid i \in I_A \land o \in O_A\} \]

where \( I_A \) and \( O_A \) are two finite and disjoint sets of inputs and outputs, respectively. We require that \( A \) is input enabled and input deterministic, i.e., for every state \( s \in S_A \) and input \( i \in I_A \), there exists precisely one output \( o \in O_A \) such that \( s \xrightarrow{(i/o)} \).

Input sequences of \( A \) are elements of \( (I_A)^* \). For \( \xi \) an input sequence of \( A \) and \( s, s' \in S_A \), we write \( s \xrightarrow{\xi} A s' \) if there exists a trace \( \sigma \) such that \( s \xrightarrow{\sigma} A s' \) and \( \xi \) is the result of projecting \( \sigma \) onto \( I_A \). In this case we write \( \text{outcome}_A(\xi, s) = \sigma \); the execution fragment \( \gamma \) with \( \text{first}(\gamma) = s \) and \( \text{trace}(\gamma) = \sigma \) is denoted by \( \text{exec}_A(s, \xi) \). A distinguishing sequence for two states \( s, s' \) of \( A \) is an input sequence \( \xi \) such that \( \text{outcome}_A(\xi, s) \neq \text{outcome}_A(\xi, s') \). We say that \( \xi \) distinguishes \( s \) from \( s' \).

In Chow’s paper, conformance is defined as the existence of an isomorphism between specification and implementation. Since we do not assume automata to be minimal, we will show the existence of a bisimulation between specification and implementation. Bisimilarity is a well-known process equivalence from concurrency theory [22]. For minimal automata, bisimilarity is equivalent to isomorphism, while for deterministic automata, bisimilarity is equivalent to equality of trace sets.

**Definition 5.2.** Let \( A \) and \( B \) be FSMs. A relation \( R \subseteq S_A \times S_B \) is a bisimulation on \( A \) and \( B \) iff

- \( R(s_1, s_2) \) and \( s_1 \xrightarrow{a} A s'_1 \) implies that there is a \( s'_2 \in S_A \) such that \( s_2 \xrightarrow{a} B s'_2 \) and \( R(s'_1, s'_2) \),
- $R(s_1, s_2)$ and $s_2 \xrightarrow{a \in A} s'_2$ implies that there is a $s'_1 \in S_A$ such that $s_1 \xrightarrow{a \in A} s'_1$ and $R(s'_1, s'_2)$.

$\mathcal{A}$ and $\mathcal{B}$ are bisimilar, notation $\mathcal{A} \equiv \mathcal{B}$, if there exists a bisimulation $R$ on $\mathcal{A}$ and $\mathcal{B}$ such that $R(s^0_A, s^0_B)$. We call two states $s_1, s_2 \in S_A$ bisimilar, notation $s_1 \equiv_A s_2$, if there exists a bisimulation $R$ on $\mathcal{A}$ (and $\mathcal{A}$) such that $R(s_1, s_2)$. The relation $\equiv_A$ is an equivalence relation on $S_A$; a bisimulation class of $\mathcal{A}$ is an equivalence class of $S_A$ under $\equiv_A$. □

The main ingredient of Chow’s test suite is a characterizing set for the specification, i.e., a set of input sequences that distinguish inequivalent states by inducing different output behavior from them. In our case, two states are inequivalent if they are non-bisimilar, i.e. have different trace sets. In the presence of symmetry we will need a characterizing set not for the entire specification automaton but only for a kernel of it. However, a kernel need not be input enabled, so two inequivalent states need not have a common input sequence that distinguishes between them. Instead we will use a characterizing set that contains for every two states of the kernel that are inequivalent in the original specification automaton, an input sequence that these states have in common in the specification and distinguishes between them.

Constructing distinguishing sequences in the specification automaton rather than in the smaller kernel is of course potentially as expensive as in the setting without symmetry, and may lead to large sequences. However, if the number of states of the kernel is small we will not need many of them, so test execution itself may still benefit considerably from the restriction to the kernel. Moreover, we expect that in most cases distinguishing sequences can be found in a well marked out subautomaton of the specification that envelopes the kernel.

**Definition 5.3.** A test pair for a Mealy machine $\mathcal{A}$ is a pair $\langle \mathcal{K}, W \rangle$ where $\mathcal{K}$ is a kernel of $\mathcal{A}$ and $W$ is a set of input sequences of $\mathcal{A}$ such that the following holds. For every pair of states $s, s' \in S_\mathcal{K}$ such that $s \not\xrightarrow{\mathcal{A}} s'$, $W$ contains an input sequence $\xi$ such that $outcome_\mathcal{A}(\xi, s) \neq outcome_\mathcal{A}(\xi, s')$. □

The proof that Chow’s test suite has complete fault coverage crucially relies on the assumption that (an upper bound to) the number of states of the black box implementation is correctly estimated. Since specification and implementation are also assumed to have the same input sets and to be input enabled, this is equivalent to a correct estimate of the number of states of the implementation that can be reached from the start state by an input sequence from the specification. Similarly, we will assume that we can give an upper bound to the number of states of the black box that are reachable from the start state by an input sequence from the kernel of the specification. We call the subautomaton of the implementation generated by these states the image of the kernel.

Technically, the assumption on the state space of the black box is used in [7] to bound the maximum length of distinguishing sequences needed for a characterizing set for the implementation. Since, like the kernel, the image of the kernel need not be input enabled, it may be that distinguishing sequences for states of the image cannot be constructed in the image itself. Thus, it is not sufficient to estimate the number of states of the image, but we must in addition estimate the number of steps distinguishing sequences may have to take outside the image of the kernel.
Definition 5.4. Let \( A \) and \( B \) be Mealy machines with the same input set and let \( K \) be a kernel of \( A \). A \( K \)-sequence is an input sequence \( \xi \) such that \( s_0^A \xrightarrow{\xi} K \). A state \( s \) of \( B \) is called \( K \)-related if there exists a \( K \)-sequence \( \xi \) such that \( s_0^B \xrightarrow{\xi} B \). We define \( \text{im}_K(B) \) as the subautomaton \((S, \Sigma, E, s^0)\) of \( B \) defined by:

- \( S = \{s \in S_B \mid s \text{ is } K \text{-related} \} \)
- \( E = \{(s, a, s') \in E_B \mid s, s' \in S \} \)
- \( \Sigma = \{a \in \Sigma_B \mid \exists s, s'. (s, a, s') \in E \} \)
- \( s^0 = s_0^B \)

Definition 5.5. A subautomaton \( B \) of a Mealy machine \( A \) is \((m_1, m_2)\)-self-contained in \( A \) when the number of bisimulation classes \( Q \) of \( A \) such that \( Q \cap S_B \neq \emptyset \) is \( m_1 \), and for every pair of states \( s, s' \) of \( B \) such that \( s \not\sim_A s' \), there exist input sequences \( \xi_1, \xi_2 \) of \( A \) of length at most \( m_1, m_2 \), respectively, such that \( s \xrightarrow{\xi_1} B, s' \xrightarrow{\xi_2} B \), and \( \text{outcome}_A(\xi_1 s_2, s) \neq \text{outcome}_A(\xi_1 s_2, s') \).

The next lemma is a generalization of [7]'s Lemma 0.

Lemma 5.6. Let \( A \) and \( B \) be Mealy machines with the same input set \( I \) and let \( \langle K, W \rangle \) be a test pair for \( A \). Let \( C = \text{im}_K(B) \). Suppose that:

1. \( C \) is \((m_1, m_2)\)-self-contained in \( B \).
2. \( W \) distinguishes between \( n \) bisimulation classes \( Q \) of \( B \) such that \( Q \cap S_C \neq \emptyset \).

Then for every two states \( s \) and \( s' \) of \( C \) such that \( s \not\sim_B s' \), \( I^{m_1 - n} I^{m_2} W \) distinguishes \( s \) from \( s' \).

Proof. By induction on \( j \in \{0, \ldots, m_1 - n\} \) we prove that there exist \( j + n \) bisimulation classes \( Q \) of \( B \) with \( Q \cap S_C \neq \emptyset \) such that \( I^j I^{m_2} W \) distinguishes between them. This proves the result, since, by assumption 1, the number of bisimulation classes \( Q \) of \( B \) such that \( Q \cap S_C \neq \emptyset \) is \( m_1 \).

- \( j = 0 \). By assumption 3, \( W \) already distinguishes between \( n \) bisimulation classes of \( B \) with \( Q \cap S_C \neq \emptyset \), so surely \( I^{m_2} W \) distinguishes at least these \( n \) classes.

- \( j = k + 1 \). If \( I^k I^{m_2} W \) already distinguishes between \( k + 1 \) bisimulation classes \( Q \) of \( B \) such that \( Q \cap S_C \neq \emptyset \), we are done. So suppose not. Then there exist two distinct bisimulation classes \( Q_1 \) and \( Q_2 \) of \( B \) whose intersection with \( S_C \) is non-empty, such that \( I^k I^{m_2} W \) does not distinguish \( Q_1 \) from \( Q_2 \). So there exist states \( s_1 \in Q_1 \cap S_C \) and \( s_2 \in Q_2 \cap S_C \) of \( C \) such that \( s_1 \not\sim_B s_2 \) but \( I^k I^{m_2} W \) does not distinguish \( s_1 \) from \( s_2 \). Since \( C \) is \((m_1, m_2)\)-self-contained in \( B \), we can define the smallest number \( l \leq m_1 \) such that \( I^l I^{m_2} W \) contains an input sequence \( \xi \) such that \( \text{outcome}_B(\xi, s_1) \neq \text{outcome}_B(\xi, s_2) \).
So there exist states \( t_1 \) and \( t_2 \) of \( C \) (among the \((l - (k + 1))^{th}\) successors of \( s_1 \) and \( s_2 \), respectively) such that \( I^k I^{m_2} W \) does not distinguish \( t_1 \) from \( t_2 \) whereas \( I^{k+1} I^{m_2} W \) does distinguish \( t_1 \) from \( t_2 \). Hence \( I^{k+1} I^{m_2} W \) distinguishes the bisimulation classes of \( B \) to which \( t_1 \) and \( t_2 \) belong.

This result allows us to construct a characterizing set \( Z = I^{m_1-n} I^{m_2} W \) for the image of the kernel in the implementation. The test suite resulting from the \( W \)-method consists of all concatenations of sequences from a transition cover \( P \) for the specification with sequences from \( Z \).

**Definition 5.7.** A transition cover for the kernel of a Mealy machine \( A \) is a finite collection \( P \) of input sequences of \( A \), such that \( \epsilon \in P \) and, for all transitions \( s \xrightarrow{\langle i,j \rangle} s' \) of \( K \), \( P \) contains input sequences \( \xi \) and \( \xi' \) such that \( s^0_K \xrightarrow{\xi} s \).

Now follows the main theorem.

**Theorem 5.8.** Let \( \text{Spec} \) and \( \text{Impl} \) be Mealy machines with the same input set \( I \), and assume \( \langle \varnothing, (\langle \rangle) \rangle \) is a symmetry on \( \text{Spec} \) such that \( \text{Impl} \) is closed under \( \varnothing \). Let \( (K, W) \) be a test pair for \( \text{Spec} \). Write \( C = \text{im}_K(\text{Impl}) \). Suppose

1. The number of bisimulation classes \( Q \) of \( \text{Spec} \) such that \( Q \cap S_K \neq \emptyset \) is \( n \).
2. \( C \) is \((m_1, m_2)\)-self-contained in \( \text{Impl} \).
3. For all \( \sigma \in P \) and \( \tau \in I^{m_1-n} I^{m_2} W \)

\[
\text{outcome}_\text{Spec}(\sigma \tau, s^0_{\text{Spec}}) = \text{outcome}_\text{Impl}(\sigma \tau, s^0_{\text{Impl}})
\]

Then \( \text{Spec} \cong \text{Impl} \).

**Proof.** \( \text{Spec} \) and \( \text{Impl} \) are deterministic, so it suffices to prove \( \text{traces}(\text{Spec}) = \text{traces}(\text{Impl}) \). Since \( \text{Spec} \) is input enabled and \( \text{Impl} \) is input deterministic, it then suffices to prove that \( \text{traces}(\text{Spec}) \subseteq \text{traces}(\text{Impl}) \). Using that \( \text{Impl} \) is closed under \( \varnothing \), this follows immediately from the first item of the following claim.

**Claim.** For every \( \sigma \in \text{traces}(\text{Spec}) \), with \( \sigma^r = \tau \) and \( s^0_K \xrightarrow{\tau} s \) \( K \) \( \tau \) we have:

1. \( \tau \in \text{traces}(\text{Impl}) \)
2. For every \( \xi \in P \) such that \( s^0_K \xrightarrow{\xi} s \) \( K \) \( \tau \) \( \text{impl} \) \( u \) and \( s^0_{\text{Impl}} \xrightarrow{\tau} s^0_{\text{Impl}} u' \) then \( u \xrightarrow{\xi} u' \).

where \( \text{I} \) abbreviates \( \text{Impl} \).
Proof of claim. Write $Z = I^{m_1-n} I^{m_2} W$. Note that, by construction of $W$, $W$ distinguishes between $n$ bisimulation classes of $Spec$ whose intersection with $S_C$ is non-empty. So, since $(*)$ holds, $W$ distinguishes between at least $n$ bisimulation classes of $Impl$ whose intersection with $S_C$ is non-empty. Thus we can use Lemma 5.6.

The proof of the claim proceeds by induction on the length $n$ of $\sigma$.

- $n = 0$. So $\sigma = \epsilon = \tau$. Then certainly $\tau \in \text{traces}(Impl)$. As to item 3), Consider an input sequence $\xi \in P$ such that $s_0^\xi \xrightarrow{\xi} \text{Spec} s_0^\xi$ and assume $s_0^\text{impl} \xrightarrow{\xi} \text{impl} u'$. We have to show that $s_0^\text{impl} \xrightarrow{\xi} u'$.

Since $\xi$ and $\epsilon$ are elements of $P$ and lead in $Spec$ to the same state, it follows from $(*)$ that for all $\rho \in Z$, $\text{outcome}_{impl}(\rho, s_0^\text{impl}) = \text{outcome}_{impl}(\rho, u')$. Hence, by Lemma 5.6, $s_0^\text{impl} \xrightarrow{\xi} u'$.

- $n > 0$. Write $\sigma = \sigma'(i/o)$. By induction hypothesis $(\sigma')^r = \tau' \in \text{traces}(\text{K}) \cap \text{traces}(\text{Impl})$. Say that $s_0^\text{impl} \xrightarrow{\tau'} u'$.

Let $s_0^\text{impl} \xrightarrow{\tau'} \text{impl} u$ and $s_0^\text{impl} \xrightarrow{\xi} \text{impl} u'$. By induction hypothesis, item 3), $u \xrightarrow{\tau} u'$. Since $\text{K}$ is a kernel of $\text{Spec}$, there exists an action $(i'/o')$ such that $(\sigma'(i/o))^r = \tau'(i'/o')$ and, for some state $r$, $r' \xrightarrow{i'/o'} \text{K} r$. Since $r' \in S_{\text{K}}$, there exist input sequences $\xi', \xi' \in P$ such that $s_0^\text{impl} \xrightarrow{\xi'} r'$.

Finally, we have to prove, for all $\xi \in P$ such that $s_0^\text{impl} \xrightarrow{\xi} \text{impl} w$, we have $w \xrightarrow{\tau} v$. Consider such a $\xi$. Since $v' \xrightarrow{\tau} v$, it suffices to prove that $w \xrightarrow{\tau} v'$. Since $\xi' \xi'$ and $\xi$ are elements of $P$ and lead to the same state in $\text{Spec}$, it follows from $(*)$ that, for all $\rho \in Z$, $\text{outcome}_{impl}(\rho, v) = \text{outcome}_{impl}(\rho, w)$.

Hence, by Lemma 5.6, $v' \xrightarrow{\tau} w$.

6 Patterns

In this section we describe symmetries based on patterns. A pattern is an FSM, together with a set of permutations of its set of actions, so-called transformations. The FSM is a template for the behavior of a system, while the transformations indicate how this template may be filled out to obtain symmetric variants that cover the full behavior of the system.

In [19] an interesting example automaton is given for a symmetric protocol, representing the behavior of two peer hosts that may engage in the ATM call setup procedure. This behavior is completely symmetric in the identity of the peers. An FSM representation is given in Figure 2. Here, $!<\text{action}>$ means output of the ATM service to caller i, and $?<$<action>$>$ means input from caller i to the ATM service. So, action $\text{set_up}(1)$ denotes the request from
caller 1 to the ATM service, to set up a call to caller 2. A set_up request is followed by an acknowledgement in the form of call_proc if the service can be performed. Then, action conn indicates that the called side is ready for the connection, which is acknowledged by conn_ack. A caller may skip sending call_proc, if it can already send conn instead (transition from state 3 to 5 and from 10 to 12 in Figure 2).

Here, a typical template is the subautomaton representing the call set up as initiated by a single initiator (e.g. caller 1), and the transformation will be the permutation of actions generated by swapping the roles of initiator and responder. Such a template is displayed in Figure 3.

In the example of Section 7, featuring a chatbox that supports multiple conversations between callers, the template will be the chatting between two callers, while the transformations will shuffle the identity of the callers.

The template FSM may be arbitrarily complex; intuitively, increasing complexity indicates a stronger symmetry assumption on the black box implementation.

To define pattern based symmetries, we need some terminology for partial functions and multisets. If \( f : A \to B \) is a partial function and \( a \in A \), then \( f(a) \downarrow \) means that \( f(a) \) is defined, while \( f(a) \uparrow \) means that \( f(a) \) is not defined. A multiset over \( A \) is a set of the form \( \{(a_1, n_1), \ldots, (a_k, n_k)\} \) where, for \( 1 \leq i \leq k \), \( a_i \) is an element of \( A \) and \( n_i \in \mathbb{N} \) denotes its multiplicity. We use \( \left[ f(x) \mid \text{cond}(x) \right] \) as a shorthand for the multiset over \( A \) that is created by adding, for every single \( x \in A \), a copy of \( f(x) \) if the condition \( \text{cond}(x) \) holds.

**Definition 6.1 (Patterns).** A pattern \( \mathcal{P} \) is a pair \( (T, \Pi) \) where \( T \) is an FSM, called the template of \( \mathcal{P} \), and \( \Pi \) is a finite set of permutations of \( \Sigma_T \), which we call transformations.

Given a sequence \( \langle f_1, \ldots, f_n \rangle \) of (partial) functions \( f_1, \ldots, f_n : \Pi \to E_T \), we denote with
exec((f_1, \ldots, f_n), \pi) \) the sequence of edges obtained by taking for each function \( f_i, \ 0 \leq i \leq n, \) the edge \( e \) (if any) such that \( f_i(\pi) = e. \)

In the remainder of this section, we fix an FSM \( A \) and a pattern \( \mathcal{P} = (T, \Pi). \)

Below we will define how \( \mathcal{P} \) defines a symmetry of the behavior of an FSM \( A. \) Each transformation \( \pi \in \Pi \) gives rise to a copy \( \pi(T) \) of \( T \) obtained by renaming the actions according to \( \pi. \) Each such copy is a particular instantiation of the template. Intuitively, the trace set of \( A \) is included in the trace set of the parallel composition of the copies \( \pi(T) \), indexed by elements of \( \Pi \), with enforced synchronization over all actions of \( A. \) Using that traces of \( A \) are traces of the parallel composition, we will define the symmetry relation on traces in terms of the behavior of the copies and permutations of the index set \( \Pi. \)

The following definition rephrases the inclusion requirement above in such a way that the relation \( \simeq \) and a representative function for it can be formulated succinctly. In particular, if \( A \) is the parallel composition of the copies of \( T, \) the requirement in this definition apply.

**Definition 6.2.** Let \( \sigma = a_1 \cdots a_n \) be an element of \((\Sigma_A)^*. \) A covering of \( \sigma \) by \( \mathcal{P} \) is a sequence \((f_1, \ldots, f_n)\) of partial functions \( f_i : \Pi \to E_T \) with non-empty domain such that for every \( \pi \in \Pi \) and \( 1 \leq i \leq n:\)

1. If \( f_i(\pi) = e \) then \( a_i = \pi(\text{act}(e)). \)
2. The sequence \( \text{exec}((f_1, \ldots, f_i), \pi) \) induces an execution \( \gamma_i \) of \( T. \)
3. If the sequence \( \text{trace}(\gamma_{i-1}) a_i \) is a trace of \( \pi(T) \) then \( f_i(\pi) \downarrow. \)

We say that \( \mathcal{P} \) covers \( \sigma \) if there exists a covering of \( \sigma \) by \( \mathcal{P}. \)

We call \( \mathcal{P} \) loop preserving when the following holds. Suppose \( \sigma_1 \sigma_2 \in \text{traces}(A) \) is covered by \((f_1, \ldots, f_n, g_1, \ldots, g_m)\) and \( \sigma_2 \) is a looping trace. Then for all \( \pi \in \Pi,\)

\[
\text{last} \left( \text{exec}((f_1, \ldots, f_n), \pi) \right) = \text{last} \left( \text{exec}((f_1, \ldots, f_n, g_1, \ldots, g_m), \pi) \right)
\]

Intuitively, these requirements mean the following. The ‘non-empty domain’ requirement for the partial functions \( f_i \) ensures the inclusion of the trace set of \( A \) in the trace set of the parallel composition of copies of \( T. \) Requirements 1 and 2 express that a covering should not contain ‘junk’. Requirement 3 corresponds to the enforced synchronization of actions of the parallel composition.

**Lemma 6.3.** For every trace \( \sigma, \) there exists at most one covering of \( \sigma \) by \( \mathcal{P}. \)

**Proof.** Since \( T \) is deterministic, coverings of \( \sigma \) are uniquely determined by \( T. \)

Two traces \( \sigma \) and \( \tau \) of the same length \( n \) that are covered by \( \mathcal{P}, \) are variants of each other if at each position \( i, \ 1 \leq i \leq n, \) of \( \sigma \) and \( \tau \) the following holds. The listings for \( \sigma \) and \( \tau, \) respectively, of the copies \( \pi(T) \) that participate in the action at position \( i, \) the states these copies are in before participating, and the edge they follow by participating, are equal up to a permutation of \( \Pi. \) Then, two traces of the same length are symmetric if they are either both not covered by \( \mathcal{P} \) or are covered by coverings that are variants of each other.
**Definition 6.4.** Let \( \sigma \) and \( \tau \) be elements of \((\Sigma_A)^n\), which \( \mathcal{P} \) covers by \( \text{cov}_1 = \langle f_1, \ldots, f_n \rangle \) and \( \text{cov}_2 = \langle g_1, \ldots, g_n \rangle \), respectively. Then \( \text{cov}_1 \) and \( \text{cov}_2 \) are said to be variants of each other if for every \( 1 \leq i \leq n \), \([f_i(\pi) \mid \pi \in \Pi] = [g_i(\pi) \mid \pi \in \Pi]\).

We define the binary relation \( \simeq \) on \((\Sigma_A)^*\) by:

\[
\sigma \simeq \tau \iff |\sigma| = |\tau| \\
\wedge \forall \text{ both } \sigma \text{ and } \tau \text{ are not covered by } \mathcal{P} \\
\vee \mathcal{P} \text{ covers } \sigma \text{ and } \tau \text{ by variant coverings}
\]

It is easy to check that \( \simeq \) is an equivalence relation. As in Section 3, we will write \([\sigma]\) for the equivalence class of \( \sigma \) and \( \simeq \) instead of \( \simeq \).

**An important special case is the following.** Suppose \( A \) consists of the parallel composition of components \( C_i \), indexed by elements of a set \( I \), that are identical up to their ID (which occur as parameters in the actions). Let \( \sigma \) and \( \tau \) be traces of \( A \). If there exists a permutation \( \rho \) of the index set \( I \) such that for all indices \( i \in I \), \( \sigma \) induces (up to renaming of IDs in actions) the same execution of \( C_i \) as \( \tau \) induces in \( C_{\rho(i)} \), then \( \sigma \) and \( \tau \) are symmetric.

**Lemma 6.5.** If \( \mathcal{P} \) covers \( \sigma a \) by \( \langle f_1, \ldots, f_n \rangle \), then \( \mathcal{P} \) covers \( \sigma \) by \( \langle f_1, \ldots, f_{n-1} \rangle \).

**Lemma 6.6.** If \( \mathcal{P} \) covers \( \sigma a \) and \( \tau b \) and \( \sigma a \simeq \tau b \), then \( \sigma \simeq \tau \).

**Proof.** Let \( \sigma a \) and \( \tau b \) be covered by \( \langle f_1, \ldots, f_n \rangle \) and \( \langle g_1, \ldots, g_n \rangle \), respectively. By Lemma 6.5, these coverings induce the coverings \( \langle f_1, \ldots, f_{n-1} \rangle \) and \( \langle g_1, \ldots, g_{n-1} \rangle \) of \( \sigma \) and \( \tau \), respectively, which are clearly variants of each other.

The previous two lemmas together imply the following result.

**Corollary 6.7.** The relation \( \simeq \) is prefix closed on \( A \), i.e., for every two traces \( \sigma a, \tau b \in \text{traces}(A) \), if \( \sigma a \simeq \tau b \) then \( \sigma \simeq \tau \).

Given the definition of \( \simeq \), it is reasonable to demand that every trace of \( A \) is covered by \( \mathcal{P} \). We will also need the following closure property. We call a binary relation \( R \) on \((\Sigma_A)^*\) persistent on \( A \) when \( R(\sigma, \tau) \) and \( \sigma a \in \text{traces}(A) \) implies that there exists an action \( b \) such that \( R(\sigma a, \tau b) \).

Now we define a representative function for \( \simeq \). We assume given a total, irreflexive ordering \( < \) on \( \Sigma_A \). Such an ordering of course always exists, but the choice for \( < \) may greatly influence the size of the kernel constructed for a symmetry based on \( \mathcal{P} \).

**Definition 6.8.** Let \( < \) be a total, irreflexive ordering on \( \Sigma_A \). This ordering induces a reflexive, transitive ordering \( \leq \) on traces of the same length in the following way:

\[
a \sigma \leq b \tau \iff a < b \vee (a = b \wedge \sigma \leq \tau)
\]

We define \( \sigma^r \) as the least element of \([\sigma]\) under \( \leq \). □
We will show that \( ()^r \) is a representative function for \( \simeq \). First we prove that \( ()^r \) is prefix closed.

**Lemma 6.9.** Suppose \( \simeq \) is persistent on \( A \) and \( A \) is closed under \( \simeq \). If \( ([\tau b])^r = \sigma a \in \text{traces}(A) \), then \( ([\tau])^r = \sigma \).

**Proof.** By contradiction. Suppose that there exists a trace \( \rho \) such that \( \rho = ([\tau])^r \) and \( \rho \neq \sigma \). Note that, since \( A \) is closed under \( \simeq \), \( \tau b \in \text{traces}(A) \). By persistence of \( \simeq \), \( \rho \in [\tau] \) implies that there exists an action \( c \) such that \( \rho c \in [\tau b] \). Since \( \simeq \) is prefix closed on \( A \) (Corollary 6.7) and \( \sigma a \in [\tau b], \sigma \in [\tau] \). By definition of \( ()^r \), \( \rho \leq \sigma \). But also, \( \sigma a \leq \rho c \), and, by definition of \( \leq \), \( \sigma \leq \rho \). So \( \rho = \sigma \) and we have a contradiction. \( \square \)

To show that \( ()^r \) is loop respecting, we first prove two auxiliary results.

**Lemma 6.10.** If \( \mathcal{P} \) covers \( \sigma \) and \( \tau \) by \( (f_1, \ldots, f_n) \) and \( (g_1, \ldots, g_n) \), respectively, and \( \sigma \simeq \tau \), then for every \( 1 \leq i \leq n \):

\[
[\text{last}(\text{exec}(\{f_1, \ldots, f_i\}, \pi)) \mid \pi \in \Pi \land f_i(\pi) \downarrow] = [\text{last}(\text{exec}(\{g_1, \ldots, g_i\}, \pi)) \mid \pi \in \Pi \land g_i(\pi) \downarrow]
\]

**Proof.** Since \( \sigma \simeq \tau \) we know that for every \( 1 \leq i \leq n \), \([f_i(\pi) \mid \pi \in \Pi] = [g_i(\pi) \mid \pi \in \Pi]\). From this the result follows immediately. \( \square \)

**Lemma 6.11.** Suppose \( \mathcal{P} \) is a loop preserving pattern on \( A \) and let \( < \) be a total, irreflexive ordering on \( \Sigma_A \). Let \( ()^r \) be as in Definition 6.8. Suppose every trace of \( A \) is covered by \( \mathcal{P} \), \( A \) is closed under \( \simeq \), and \( \simeq \) is persistent on \( A \). If \( \sigma_1 \sigma_2 \sigma_3 \in \text{traces}(A) \) and \( \sigma_2 \) is a looping trace, then

\[
\sigma_1 \sigma_3 \simeq \sigma_1 \tau \iff \sigma_1 \sigma_2 \sigma_3 \simeq \sigma_1 \sigma_2 \tau.
\]

**Proof.** Write \(|\sigma_1| = n, |\sigma_2| = m, \) and \(|\sigma_3| = |\tau| = k \). Let \( \langle f_1, \ldots, f_n, g_1, \ldots, g_m, h_1, \ldots, h_k \rangle \) cover \( \sigma_1 \sigma_2 \sigma_3 \). By Lemma 6.5, \( \langle f_1, \ldots, f_n, g_1, \ldots, g_m \rangle \) covers \( \sigma_1 \sigma_2 \) and \( \langle f_1, \ldots, f_n \rangle \) covers \( \sigma_1 \). Since \( \simeq \) is loop preserving on \( A \), we know that for every \( \pi \in \Pi \)

\[
\text{last}(\text{exec}(\{f_1, \ldots, f_n, \pi\})) = \text{last}(\text{exec}(\{f_1, \ldots, f_n, g_1, \ldots, g_m, \pi\}))
\]

(1)

So \( \langle f_1, \ldots, f_n, h_1, \ldots, h_k \rangle \) covers \( \sigma_1 \sigma_3 \).

\( \Rightarrow \) Since \( \sigma_1 \sigma_3 \simeq \sigma_1 \tau \) and \( \sigma_1 \sigma_3 \in \text{traces}(A) \), \( \sigma_1 \tau \in \text{traces}(A) \). Let \( \langle f_1, \ldots, f_n, h'_1, \ldots, h'_{k} \rangle \) cover \( \sigma_1 \tau \). From Equation 1 and the fact that \( \langle f_1, \ldots, f_n, g_1, \ldots, g_m \rangle \) covers \( \sigma_1 \sigma_2 \), it follows that \( \langle f_1, \ldots, f_n, g_1, \ldots, g_m, h'_1, \ldots, h'_k \rangle \) covers \( \sigma_1 \sigma_2 \tau \). Since \( \sigma_1 \sigma_3 \simeq \sigma_1 \tau \), we obtain, for every \( 0 \leq i \leq k \):

\[
[h_i(\pi) \mid \pi \in \Pi] = [h'_i(\pi) \mid \pi \in \Pi]
\]

(2)

From this fact, it follows that \( \sigma_1 \sigma_2 \sigma_3 \simeq \sigma_1 \sigma_2 \tau \).
Since \( \sigma_1 \sigma_2 \sigma_3 \simeq \sigma_1 \sigma_2 \tau \) and \( \sigma_1 \sigma_2 \sigma_3 \in \text{traces}(A) \), \( \sigma_1 \sigma_2 \tau \in \text{traces}(A) \).

Let \( \langle f_1, \ldots, f_n, g_1, \ldots, g_m, h'_1, \ldots, h'_k \rangle \) cover \( \sigma_1 \sigma_2 \tau \). From Equation 1, it follows that \( \langle f_1, \ldots, f_n, h'_1, \ldots, h'_k \rangle \) covers \( \sigma_1 \tau \). Since \( \sigma_1 \sigma_2 \sigma_3 \simeq \sigma_1 \sigma_2 \tau \), we obtain, for every \( 0 \leq i \leq k \):

\[
[h_i(\pi) \mid \pi \in \Pi] = [h'_i(\pi) \mid \pi \in \Pi]
\]  

(3)

From this, it follows that \( \sigma_1 \sigma_3 \simeq \sigma_1 \tau \).

Finally, we prove that \( (\cdot)^r \) is loop respecting.

**Lemma 6.12.** Suppose \( P \) is a loop preserving pattern on \( A \) and let \( < \) be a total, irreflexive ordering on \( \Sigma_A \). Let \( (\cdot)^r \) be as in Definition 6.8. Suppose every trace of \( A \) is covered by \( P \), \( A \) is closed under \( \sim \), and \( \sim \) is persistent on \( A \). If \( ([\sigma_1 \sigma_2 \sigma_3])^r = \sigma_1 \sigma_2 \sigma_3 \in \text{traces}(A) \) and \( \sigma_2 \) is a looping trace, then \( ([\sigma_1 \sigma_3])^r = \sigma_1 \sigma_3 \).

**Proof.** By contradiction. Suppose that \( ([\sigma_1 \sigma_3])^r = \tau_1 \tau_3 \) and \( \tau_1 \tau_3 \neq \sigma_1 \sigma_3 \). By Lemma 6.9, \( ([\sigma_1])^r = \sigma_1 \), and \( \tau_1 = ([\sigma_1])^r \), so \( \tau_1 = \sigma_1 \). By definition of \( (\cdot)^r \), \( \sigma_1 \tau_3 \leq \sigma_1 \sigma_3 \) and \( \sigma_1 \tau_3 \simeq \sigma_1 \sigma_3 \). By Lemma 6.11, \( \sigma_1 \sigma_2 \sigma_3 \simeq \sigma_1 \sigma_2 \tau_3 \). Since \( \sigma_1 \sigma_2 \sigma_3 = ([\sigma_1 \sigma_2 \sigma_3])^r \), \( \sigma_1 \sigma_2 \sigma_3 \leq \sigma_1 \sigma_2 \tau_3 \), and by definition of \( \leq \), \( \sigma_1 \sigma_3 \leq \sigma_1 \tau_3 \). Since also \( \sigma_1 \tau_3 \leq \sigma_1 \sigma_3 \), \( \sigma_1 \tau_3 = \sigma_1 \sigma_3 \), and we have a contradiction. So \( \sigma_1 \sigma_3 = ([\sigma_1 \sigma_3])^r \).

The next result allows us to use the pattern-approach for computing a kernel. In our example of the ATM switch, we have computed the kernel from the FSM in Figure 2, using the symmetry induced by the template in Figure 3 and an ordering \( < \) that obeys the relation \( \text{set}_\text{up}(1) < \text{set}_\text{up}(2) \). Not surprisingly, the resulting kernel is identical to the template.

**Theorem 6.13.** Suppose \( P \) is a loop preserving pattern on \( A \) and let \( < \) be a total, irreflexive ordering on \( \Sigma_A \). Let \( (\cdot)^r \) be as in Definition 6.8. Suppose every trace of \( A \) is covered by \( P \), \( A \) is closed under \( \sim \), and \( \sim \) is persistent on \( A \). Then \( (\sim, (\cdot)^r) \) is a symmetry on \( A \).

**Proof.** We have to show that \( (\cdot)^r \) is a representative function for \( \sim \). It is immediate that \( \sigma^r \simeq \sigma \) and for all \( \tau \) such that \( \sigma \simeq \tau \), \( \tau^r = \sigma^r \). The requirement that \( (\cdot)^r \) is prefix closed follows from Lemma 6.9. That \( (\cdot)^r \) is loop respecting follows from Lemma 6.12.

The following lemma is an extra ingredient for making the implementation of the algorithm Kernel from Section 4 more efficient. The implementation itself is described in Section 7.

**Lemma 6.14.** Suppose \( P = (\mathcal{T}, \Pi) \) is a pattern on \( A \), that covers \( \sigma \) and \( \tau \) by \( \langle f_1, \ldots, f_n \rangle \) and \( \langle g_1, \ldots, g_m \rangle \), respectively.

If \( s^0 \xrightarrow{\sigma} A s \), \( s^0 \xrightarrow{\tau} A s \) and \( \forall \pi \in \Pi. \text{last}(\text{exec}(\langle f_1, \ldots, f_n \rangle, \pi)) = \text{last}(\text{exec}(\langle g_1, \ldots, g_m \rangle, \pi)) \),

then for each \( \rho \) such that \( s \xrightarrow{\rho} A \):

\( \langle f_1, \ldots, f_n, h_1, \ldots, h_k \rangle \) covers \( \sigma \rho \iff \langle g_1, \ldots, g_m, h_1, \ldots, h_k \rangle \) covers \( \tau \rho \).
Lemma 6.15. Suppose $\langle \mathcal{P}, (\cdot)\rangle$ is a symmetry on $\mathcal{A}$, $(\cdot)'$ is as in Definition 6.8, and $\mathcal{P} = \langle \mathcal{A}, \Pi \rangle$ covers $\sigma$ and $\tau$ by $(f_1, \ldots, f_n)$ and $(g_1, \ldots, g_m)$, respectively. If $s_0^0 \xrightarrow{\sigma} A s, s_0^0 \xrightarrow{\tau} A s, \forall \tau \in \Pi. \text{last}(\text{exec}(\langle f_1, \ldots, f_n \rangle, \pi)) = \text{last}(\text{exec}(\langle g_1, \ldots, g_m \rangle, \pi))$, and $\sigma = \sigma'$ and $\tau = \tau'$, then for each $\rho$ such that $s \xrightarrow{\rho} A$:

$$\sigma \rho = (\sigma \rho)' \Leftrightarrow \tau \rho = (\tau \rho)'$$

Proof. We only prove "$\Rightarrow$", the other direction then follows immediately.

By contradiction. Suppose $s \xrightarrow{\rho} A, \sigma \rho = (\sigma \rho)'$ and $(\tau \rho)' = \tau \rho'$ with $\rho \neq \rho'$. By definition of $(\cdot)'$, we know that $\tau \rho \simeq \tau \rho'$. By Lemma 6.14, we know that the covering of the $\rho$-part in $\tau \rho$ must be equal to the covering of the $\rho$-part in $\sigma \rho$, and likewise for the $\rho'$-part in $\tau \rho'$ and $\sigma \rho'$. Then certainly $\sigma \rho \simeq \sigma \rho'$ must hold. By unicity of representatives, $\sigma \rho = (\sigma \rho)'$. From Definition 6.8 we then obtain that $\sigma \rho \leq \sigma \rho'$ and $\tau \rho' \leq \tau \rho$, so $\rho \leq \rho'$ and $\rho' \leq \rho$. This yields a contradiction with the assumption that $\rho \neq \rho'$.

7 Example: Testing a chatbox

In this section we report on some initial experiments in the application of symmetry to the testing of a chatbox. Part of the test generation trajectory was implemented: we used the tool environment OPEN/CÆSAR[14] for prototyping the algorithm Kernel from Section 3. We work with a pattern based symmetry (Section 6) and apply the test derivation method from Section 5.

A chatbox offers the possibility to talk with users connected to the chatbox. After one joins (connects to) the chatbox, one can talk with all other connected users, until one leaves (disconnects). One can only join if not already present, and one can leave at any time. For simplicity, we assume that every user can at each instance talk with at most one user. Moreover, we demand that a user waits for a reply before talking again (unless one of the partners leaves). Finally, we abstract from the contents of the messages, and consider only one message. The service primitives provided by the chatbox are thus the following: Join, Leave, DReq, and DInd, with the obvious meaning (see Figure 4). For lack of space, we do not give the full formal specification of the chatbox or its template.

What we test for is the service of the chatbox as a whole, such as it may be offered by a vendor, rather than components of its implementation, which we (the “customers”) are not allowed to, or have no desire to, inspect.

This example was inspired by the conference protocol presented in [24]. Some changes were made, all stemming from the need to keep the protocol manageable for experiments without losing the symmetry pursued. We mention the absence of queues and multicasts and the restriction to the number of outstanding messages. Also, we ignore the issues of test contexts, test architectures, and points of control and observation.

The symmetry inherent in the protocol is immediate: pairs of talking users can be replaced by other pairs of talking users, as long as this is done systematically according to Definitions 6.2 and 6.4. As an example, the trace in which user 1 joins, leaves and joins again, is symmetric to the trace in which user 1 joins and leaves, after which user 2 joins. The essence is that after user 1 has joined and left, this user is at the same point as all the other users not
present, so all new join actions are symmetric. Note that this symmetry is more general than a symmetry induced solely by a permutation of actions or IDs of users. Thus the template \( T \) used for the symmetry basically consists of the conversation between two users, including joining and leaving, while the transformations \( \pi \) in the set \( \Pi \) shuffle the identity of users. We feel that it is a reasonable assumption that the black implementation offering the service indeed is symmetric in this sense.

We have applied the machinery to chatboxes with up to 4 users. We also considered a (much simpler) version of the protocol without joining and leaving. Still, a chatbox with only 4 users and no joining or leaving already has 4096 reachable states.

We start the test generation by computing a kernel for these specifications. Our prototype is able to find a significantly smaller Mealy machine as a kernel for each of the models, provided that it is given a suitable ordering \(<\) (see Definition 6.8) on the actions symbols for its representative function. The kernels constructed consist of interleavings of transformations of the pattern, constrained by the symmetry and the ordering \(<\).

For instance, in a chatbox with 3 users and no joining and leaving, we take the ordering \(<\) defined as follows. “Sending a message from \( i_1 \) to \( j_1 \)” \(<\” sending a message from \( i_2 \) to \( j_2 \)” if \( (i_1 < i_2) \) or if \( (i_1 = i_2 \) and \( j_1 < j_2 \)), and “sending a reply from \( i_1 \) to \( j_1 \)” \(<\” sending a reply from \( i_2 \) to \( j_2 \)” if \( (i_1 > i_2) \) or if \( (i_1 = i_2 \) and \( j_1 > j_2 \)).

Using this ordering, the kernel only contains those traces in which first messages from user 1 are sent, then messages from user 2 and finally messages from user 3, while the sending of replies is handled in the reverse order. Each trace with different order of sending messages can then be computed from a trace of this kernel, which is exactly what Theorem 4.8 states. This technique of dealing with traces is reminiscent of partial order techniques [16].

Our experiments so far have revealed that for chatboxes with joining and leaving, the kernel is approximately half the size. When considering chatboxes without joining and leaving, the size of the kernel is reduced much more. This difference is due to the fact that, since one cannot send a message to a user that has left, joining and leaving obstructs the symmetry in messages being sent. Of course, the algorithm should be run on more and larger examples to get definite answers about possible size reduction.

Given the computed kernels, we can construct test pairs by determining for each kernel a set of input sequences \( W \) that constitutes a characterizing set for the kernel (as defined in Definition 5.3). Although this part has not yet been automated, it is easily seen by a generic
argument that for every pair of inequivalent (non-bisimilar) states very short distinguishing
sequences exist. It is easy to devise a transition cover for a kernel, the size of which is
proportional to the size of the kernel.

As shown in Theorem 5.8, the size of the test suite to be generated will depend on the mag­
nitude of two numbers \(m_1\) and \(m_2\), indicating the search space for distinguishing sequences
for the image of the kernel in the implementation. This boils down to the following questions:
(1) What is the size of the image part of the implementation for this kernel? (2) What is the
size of a minimal distinguishing experience for each two inequivalent (non-bisimilar) states in
the image part of the implementation? (3) How many steps does a distinguishing sequence
perform outside the image of the kernel? These questions are variations of the classical state
space questions for black box testing. For practical reasons, these numbers are usually taken
to be not much larger than the corresponding numbers for the specification.

The algorithm Kernel (see Figure 1) was implemented using the Open/C\(\xi\)SAR\ [14]\ tool
set. An interesting detail here is that the algorithm uses two finite state machines: one
for the specification that is reduced to a kernel, and one for the template of the symmetry,
which is used to determine (as an oracle) whether two traces are symmetric. To enable this,
Open/C\(\xi\)SAR interface had to be generalized somewhat so that it is now able to explore sev­
eral labeled transition systems at the same time. We have the experience that Open/C\(\xi\)SAR
is suitable for prototyping exploration algorithms such as Kernel.

8 Future work

We have introduced a general, FSM based, framework for exploiting symmetry in speci­
fications and implementations in order to reduce the amount of tests needed to establish
correctness. The feasibility of this approach has been shown in a few experiments.

However, a number of open issues remain. We see the following steps as possible, necessary
and feasible. On the theoretical side we would like to (1) construct algorithms for computing
and checking symmetries, and (2) determine conditions that are on the one hand sufficient
to guarantee symmetry, and on the other hand enable significant optimizations of the algo­
rithms. On the practical side we would like to (1) generate and execute tests for real-life
implementations, and (2) continue prototyping for the whole test generation trajectory.

Acknowledgments

We thank Frits Vaandrager for suggesting the transfer of model checking techniques to test
theory, and Radu Mateescu and Hubert Garavel for their invaluable assistance (including
adding functionality!) with the Open/C\(\xi\)SAR tool set. We also thank Jan Tretmans and
the anonymous referees for their comments on this paper.
