This research was supported by the Dutch Council for Health and Society (Raad voor Volksgezondheid en Samenleving, RVS), a strategic advisory council for the Dutch government and employer of the first author. The Council for Health and Society provided financial support for the conduct of this research and the preparation of this article, but had no role in the study design, the collection, analysis and interpretation of data, in the writing of this article or the decision to submit it for publication.

Abstract

Background: To meet the challenge of multimorbidity in decision making, a switch from a disease-oriented to a goal-oriented approach could be beneficial for patients and clinicians. More insight about the concept and the implementation of this approach in clinical practice is needed.

Objective: This study aimed to develop conceptual descriptions of goal-oriented care by examining the perspectives of general practitioners (GPs) and clinical geriatricians (CGs), and how the concept relates to collaborative communication and shared decision making with elderly patients with multimorbidity.

Method: Qualitative interviews with GPs and CGs were conducted and analyzed using thematic analysis.

Results: Clinicians distinguished disease- or symptom-specific goals, functional goals and a new type of goals, which we labelled as fundamental goals. “Fundamental goals” are goals specifying patient’s priorities in life, related to their values and core relationships. These fundamental goals can be considered implicitly or explicitly in decision making or can be ignored. Reasons to explicate goals are the potential mismatch between medical standards and patient preferences and the need to know individual patient values in case of multimorbidity, including the management in acute situations.

Conclusion: Based on the perspectives of clinicians, we expanded the concept of goal-oriented care by identifying a three-level goal hierarchy. This model could facilitate collaborative goal-setting for patients with multiple long-term conditions in clinical practice. Future research is needed to refine and validate this model and to provide specific guidance for medical training and practice.

Keywords
collaborative goal-setting, decision making, elderly, fundamental goals, goal-oriented care, multimorbidity
Interest in goal-oriented care is increasing among policy makers and clinicians alike.\textsuperscript{1-7} Goal-oriented care is particularly important where patients have multiple long-term conditions, known as multimorbidity. Multimorbidity is defined as the coexistence of two or more chronic diseases or conditions, and its incidence is causing a challenge to health-care systems, patients and medical practitioners. In daily medical practice, multimorbidity challenges decision making in several ways. Disease priorities can be interfering\textsuperscript{8,9} and the need of adherence to multiple disease guidelines can be problematic.\textsuperscript{10} Disease-specific guidelines are often not applicable to older patients with multiple conditions\textsuperscript{9,11,12} and compliance to multiple single disease guidelines can result in polypharmacy, high treatment burden, inattention to social and personal context and failure to align care with personal goals and preferences.\textsuperscript{13,14} Having multiple chronic conditions often leads to the involvement of several clinicians, who concentrate on managing different conditions and monitoring different disease-specific outcomes. Patients are at risk of receiving fragmented care that might lack focus on what matters most to them.\textsuperscript{7} Focusing care on what matters most to patients could be helpful but is also a challenge in itself.

Aligning health outcomes with individuals’ values is complex, especially for older adults with multiple chronic morbidities facing conditions with clinical uncertainty (eg cancer).\textsuperscript{15-17} Clinicians are challenged in helping people prioritize their values, define treatment goals and frame preferences in ways that are clinically relevant and aligned with one’s values when faced with multiple diagnostic and treatment options.\textsuperscript{18,19} Patients and clinicians may also differ in perspectives and priorities in this respect.\textsuperscript{6,9,16,19,22} Clinicians are at risk to make inaccurate assumptions about patient values and preferences\textsuperscript{5} and may think that they know what is best for patients.\textsuperscript{10} It is clear that in care for older patients with multimorbidity, incorporating values and preferences in decision making is necessary to focus on what matters most to them, but in daily practice this is complex.

To meet the challenges of multimorbidity care, including the necessary incorporation of values and preferences, Tinetti et al\textsuperscript{2} proposed a shift from a disease-oriented to a goal-oriented approach. Taking this approach, it seems health goals can be defined using a range of dimensions (eg symptoms; physical functional status, including mobility; and social role). In goal-oriented health care, care is personalized to accommodate patients’ goals, preferences and resources.\textsuperscript{3,22} Collaborative goal-setting (CGS), defined as “a process by which health-care professionals and patients agree on a health-related goal”,\textsuperscript{15} can be useful for personalizing care and encourages patient involvement in the goal-setting process. CGS has been evaluated in several rehabilitation settings.\textsuperscript{24-27} However, CGS in the context of older patients with multimorbidity is not common practice yet. In the 2014 Commonwealth Fund Survey of adults aged 65 or older and having a chronic condition, rates of respondents reporting the sharing goals with a professional varied from 23% (Sweden), till 59% (United Kingdom). Nine of 11 countries were having rates of less than 50% of respondents reporting the sharing goals with a professional.\textsuperscript{28} There appears to be a relative lack of insight in goal-setting processes in the presence of complexity and little evidence to support best practices in goal-setting with complex patients.\textsuperscript{29} Furthermore, as concluded by Knight et al, the concepts of values, goals and preferences are often used interchangeably,\textsuperscript{30} indicating a need for establishing consistent definitions. In the Netherlands, the current views of general practitioners (GPs) and clinical geriatricians (CGs) on the concepts of goals and CGS are as yet unknown. These views could provide valuable input into the concept of goal-orientation and into the perceived relevance of the approach in clinical practice. The objective of this study was to examine the concept of goal-orientation from a clinician’s perspective, in the context of CGS and shared decision making (SDM), where patients have multiple long-term conditions.

2 | METHOD

2.1 | Participants

This qualitative study was conducted by inviting CGs and GPs to participate in semi-structured interviews. Participants were selected using a purposive and snowball method, aiming to recruit professional experts, and contacted by email. We invited experienced GPs and CGs performing research, teaching, developing or implementing specific innovations in care for older patients. The first two participants were acquaintances of the interviewer (first author). Some GPs were recruited at a meeting of GPs holding a specialization in geriatric care. In the sampling, we aimed to recruit comparable numbers of CGs and GPs. To obtain diverse perspectives, we tried to ensure that different types of practice and practice location (rural or urban) for GPs and different types of hospitals (CGs) would be represented. Furthermore, we tried to ensure that all Dutch regions would be represented as much as possible. The response rates of CGs and GPs approached were 86% and 54%, respectively. The final sample consisted of 18 CGs and 15 GPs.

2.2 | Procedures

An interview guide (Table 1) was inspired by two perspectives on goal-oriented health care for elderly patients with chronic multimorbidity\textsuperscript{2,3} and professional experiences (general practice and clinical geriatrics) in our research team. Two pilot interviews were conducted with a CG and a GP. Main topics and subtopics were not changed based on the pilot interviews nor during the conducting of the interviews. The interview guide covered three main topics: CGS, SDM and effective collaborative action. We defined effective collaborative action as clinicians and patient deciding on and performing diagnostic and treatment steps in line with collaborative goals, which were set between patient and clinicians or with other involved caretakers. Definitions were not given to the interviewees. At the start of the interview, the clinicians were asked to use the context of regular care for community-dwelling older patients (age >75 years) with a chronic disease or multimorbidity without further specifications. It was also suggested to keep one or more cases in mind in answering the questions. All topics and subtopics were covered in all interviews.
Browse the two final interviews confirmed theoretical saturation as they were drafted throughout the data collection and analysis process. Detailed field notes were made after each interview. Theoretical interpretations of aspects of the research topic. In an inductive approach, data-driven, an iterative process of interviewing and analysis was followed. During the interviewing phase, preliminary analyses were conducted based on reflections and discussion of the interviews (first and last author) and by constantly comparing the interviews with the field notes. These preliminary analyses were conceived in theoretical memos, and the interview guide was continually compared, discussed, grouped and categorized to develop an initial coding tree. The first five interviews were coded independently by both data coders. The remaining interviews were coded by one researcher (second author) and checked by the other (first author). In weekly meetings, the researchers (first and second author) compared, discussed and agreed on the coding of the transcripts, including the creation of additional codes and further refinement of categories and subcategories. Similarities, differences, regularities and patterns were interpreted and discussed to identify themes and to generate hypotheses. Illustrative quotations were selected to underpin and illustrate our findings. In addition, Box 1 presents two case examples, one of a GP and one of a CG to illustrate daily practice of this topic.

The quotations were translated from Dutch into English by a professional translator. The translator and first author discussed the translations to ensure that proper meaning of words and nuances were kept in the translation process. For data coding and analysis, Atlas-ti 7.1.15, (GmbH, Berlin, Germany), was used.

2.4 | Quality assurance

The Consolidated Criteria for Reporting Qualitative Research (COREQ) and a 15-point checklist for thematic analysis by Braun and Clarke were used for design, performance and reporting.31,32 Appendix S1 reports on these COREQ criteria in relation to our research. All interview topics were analyzed in one process to secure consistency and theoretical interrelatedness.

3 | RESULTS

Participating GPs’ (n = 15) mean age was 51 years, being 40% male and on average having 16 years of professional experience. Participating CGs (n = 18) had a mean age of 48 years, being 50% male, and having on average 10 years of professional experience. Further participants’ characteristics are presented in Table 2. Three themes were identified (Box 2).

3.1 | Clinicians draw distinctions between different types of goals

From the data, three types of goals were identified, that is disease-specific or symptom-specific goals, functional goals and a third category labelled as fundamental goals.

Fundamental goals were described as goals specifying a patient’s priorities in life, such as their values and core relationships, topics, that serve as reference points for decision making. These are goals considering the patient’s personal views on what constitutes quality of life. Fundamental goals concern questions such as: “What makes your life worth living?”, “How do you lead your life?”, “What are your views on end of life?”; “How do you feel about quality of life vs lengthening of life?”. Examples provided by medical practitioners include: “being of help to others and/or society”, and “no wish for changes”.
"Being able to continue living independently" is a goal often mentioned by patients, according to medical practitioners, for example CG_29:

Almost invariably, the main goal for this target group is to continue living independently (…) And that ability to continue living independently is frequently more important to [patients] than being treated in a residential care facility or nursing home. (CG_29)

Fundamental goals reflect a patient’s view on their own future in the broadest sense.

Functional goals were described as goals related to reducing limitations in functioning. Examples include “being able to wash or dress oneself”, “driving a car”, and “staying mobile”. GP_06 described functional goals as follows:

What is important and what should we focus on? (…) Is it an issue if people are only able to go to a convenience store or supermarket? Or is the problem that they cannot go to their home? (GP_06)

Disease-specific or symptom-specific goals are goals relating to the diagnosis or treatment of a specific disease or symptom. Patients may ask for example for the reduction in distress caused by symptoms like shortening of breath, itching or pain. In a goal-setting process, clinician and patient can set a patient symptom-specific goal together, which incorporates personal choices in diagnostic trajectories and treatments. Some patients, for example, do not want to engage in all kinds of diagnostic trajectories as long as a certain symptom can be reduced by a certain symptomatic treatment. Other patients want to know what is causing the symptom. This type of goals can also originate from a certain disease. An example is a patient asking for disease-specific medication, as mentioned by CG_21:

These goals vary largely per patient. They can be very explicitly related to the disease. Conceivably, for instance, a patient may make a very specific request for ‘a pill against dementia’. (CG_21)

3.2 | The consideration of fundamental goals

The practitioners differed in their consideration of fundamental goals, creating three orientation categories, that is (i) no consideration of fundamental goals, (ii) implicit consideration of fundamental goals and (iii) explicit consideration of fundamental goals.

3.2.1 | No consideration of fundamental goals

Practitioners in this category mentioned a primary focus on functional goals and/or disease-specific or symptom-specific goals. Functional goals and disease-specific or symptom-specific goals can be connected to each other as described by CG_12:
Those patients usually come to me with problems (...). Their complaints vary from “more trouble walking” to “tiring out faster”, “forgetfulness”, “falling” and a whole range of other problems. You try to unravel all their problems and often come back to their medical diagnosis. At that point, you try to figure out how you can help. But the foundation is still the patient’s functioning (...). (CG_12)

The practitioners in this category did not mention setting or taking into account fundamental goals.

### 3.2.2 Implicit consideration of fundamental goals

Practitioners in this category were aware of fundamental goals. However, these goals were presumed but not made explicit in a discussion with the patient. GP_04 illustrates that they are aware of implicit fundamental goals while focusing on quality of life:

At present, what I really find important is that we mainly focus on the quality of life of the elderly and take into account their opinions and preferences. In terms of actual practice, I cannot say that my colleague and I have specific discussions [with our patients] on a regular basis about the goals patients want to pursue in their life. However, based on the questions asked, we do pay attention to what is feasible for patients. We are also cautious when it comes to adding any new medicine, having in mind the issue of multiple medications and their side effects. It is a matter of weighing up everything very carefully. When it comes to elderly patients, it is important to figure out whether all interventions will benefit them. (GP_04)

### 3.2.3 Explicit consideration of fundamental goals

The third category constitutes practitioners who have an orientation towards disease-specific and/or functional goals, while explicitly...
taking fundamental goals into account. If fundamental goals are discussed and made explicit, other goals can be set in accordance with these fundamental goals, as illustrated by the following example from daily practice of the importance of quality of life as a reference point in decision making. What quality of life means to a specific patient, can only be assessed by that specific patient:

Now imagine I discover that someone has cancer and maybe I can still help them (...) in a way that allows the patient to live a few months longer. But then, of course, there is still the decision whether or not to treat him (...). Or do you choose limited treatment? That is something that must be agreed upon with specialists, the patient and, of course, with me (...). The core issue remains the quality of life. And (...) of course that is something I can assess, at least to a certain extent, but this will primarily be done by the patient. (GP_10)

This theme “The consideration of fundamental goals” makes clear that although aspects of implicit fundamental goals may be taken into account, discussion and consideration of aspects of explicit fundamental goals, are not regular practice yet. Table 3 provides several quotations of questions asked to elicit fundamental goals, as mentioned by the practitioners. These practitioners’ examples were transformed by the authors into possible questions, which may be helpful to use in clinical practice to start a discussion on fundamental goals.

### 3.3 | The relevance of explicit goals for decision making

The analysis revealed several reasons to explicate fundamental goals. The patient’s preferences are not always in line with medical standards, nor with the preferences of the practitioners involved, as is illustrated by CG_03:

I really do believe that care will become better for the patient, that they will finally get the care they want instead of the care that guidelines, or we together, say they must be given, whereas that is not what they want. (CG_03)

Secondly, patients’ preferences may vary. For example, CG_17 describes differences in medication preferences in a case of dementia:

**TABLE 3** Example questions for collaborative fundamental goal-setting

<table>
<thead>
<tr>
<th>Example questions</th>
<th>Quotations</th>
</tr>
</thead>
<tbody>
<tr>
<td>How do you see your future? How would you prefer to plan it?</td>
<td>GP_15: I mean, you have to consider how these individuals see their future (...) and how they prefer to shape that future....</td>
</tr>
<tr>
<td>Where are you from and to what extent does spirituality play a role in your life? How do you envision the end of your life?</td>
<td>GP_21: On the one hand, I ask everyone over 75 about their core values and quality-of-life values. As for the extent of their spiritual experiences, and where they come from (...), we are not in a position to deal with that (...). Regarding quality-of-life values, those tend to relate to things like whose children visit first or (...) whether the garden is still blooming, etc. (...) Based on the core values and quality of life and other [things], we can retrieve a clear picture. At any rate, there is a lot of similarity. Is advance care planning more of a medical process? (...) If so, how do you start your daily life and how exactly do you end it? (...) When do you want that to happen? (...) This is what the patients’ vision of the end of their life entails (...) in terms of core values and quality-of-life values</td>
</tr>
<tr>
<td>What is important to you? What do you want and what do you want to avoid? What do you consider important? What are you afraid of?</td>
<td>CG_17: “What do I find important?”; “What do you really want and what do you want to avoid?”; “What do you consider important?”; “What are you afraid of?”</td>
</tr>
<tr>
<td>What are your goals and what do you want from life, specifically?</td>
<td>GP_10: “What are your goals and what do you want from life, specifically?” This question is obviously very essential. The first things that come to mind, of course, are end-of-life decisions, such as entering a nursing home, continue living independently, undergoing euthanasia or refusing it. That period, however, is just one aspect, and it comes at the very end. Before that point, there is so much more: decisions about how to live and whether or not to accept medical treatment. So the decision-making process concerns treatment, referral, end of life and place of residence</td>
</tr>
</tbody>
</table>

The example questions are based on illustrative examples given by the interviewees.
Some people are keen to try this medication which might improve their memory (...) But there are also people who say: “If it leads to weight loss or gives me skin problems, then I don’t want it”. (CG_17)

In the event of multimorbidity, the consideration of goals is even more important. The more complicated a patient’s situation, the more important it is to incorporate what constitutes quality of life to a patient in decision making as described by GP_28:

The more complicated the situation, that is the more medical issues someone is suffering from, the more the focus lies on quality of life and on the interaction between various conditions and what that means to someone (...). Then, it becomes more important to know what patients want for themselves, as it is important to have ideas about that (...). So basically, the larger the extent of multimorbidity, the more important it is to know what is important to the patient. (GP_28)

A discussion of fundamental goals can be helpful to make this meaning of quality of life, what people want for themselves in a broader sense and what is important to someone, explicit. Finally, discussing fundamental goals explicitly can provide important information for acute situations that may occur in the future, as is emphasized by CG_14:

When it comes to vulnerable elderly people, the circumstances that require you to make important decisions often arise unexpectedly (...). This may happen, for instance, when their regular doctor is absent and a different doctor is on duty (...) or by an emergency doctor in the hospital (...). When these situations occur, it is really helpful to be able to rely on information you have exchanged earlier on. (CG_14)

4 | DISCUSSION

4.1 | Main findings

The case examples (Box 1) demonstrate the importance and difficulties of aligning care with patients’ personal histories, values and priorities. Our analysis revealed three types of goals: disease-specific or symptom-specific goals, functional goals and a third type of goals, which we labelled fundamental goals. From our analysis followed that fundamental goals are implicitly and explicitly applied in daily practice. We hypothesize that the explicit setting and application of fundamental goals could lead to patient-specific clinical decisions concerning diagnostic trajectories or treatments by translating values, personal history and core relationships into useable reference points for decision making.

4.2 | Interpretation

Earlier studies confirmed our findings. Maintaining (functional) independence, fixing specific symptoms or functional challenges, day-to-day functioning, behaviour and emotional health and safety are considered important goals and priorities. An analysis of health-related values of multimorbid cancer survivors revealed the five values: self-sufficiency, life enjoyment, connectedness and legacy, balancing quality and length of life, and engagement of care. Incorporating patient values into health-care decisions is critical, especially for elderly patients since goals may change when life expectancy shortens. However, there appears to be a lack of consistency in the use of the concepts of values, goals and preferences. Naik et al make a distinction between values and health-care goals, whereby goals and preferences are seen as more context or circumstance specific. Values usually are stable and can be seen as fundamental beliefs about one’s self and life. Our findings are consistent with the importance and guiding role of values, as stated by Naik et al. However, although most people would intuitively agree with the importance of incorporating values in decision making, this seems to be not an easy ‘job’. Insight in approaches to actually clarify values and elicit patient preferences in a structured and consistent manner is lacking.

As a synthesis of the three themes identified from the data, Figure 1 represents a three-goal model for clinical practice showing three levels of relevant goals in caring for elderly with multimorbidity. Within this three-goal model, types of goals are interrelated, with disease-specific or symptom-specific goals flowing from functional goals, and both flowing from fundamental goals. Symptom-specific goals, for example, incorporate personal choices in diagnostic trajectories and treatments. These personal choices are based on aspects like beliefs, personal history, core relationships, values and functioning. Explicit fundamental and functional goals represent these aspects and are thereby useful in the related goal-setting process of symptom- or disease-specific goals.

Fundamental goals can be seen as a translation of elements like values, core relationships and priorities in life, into concrete goals. If, for example, both autonomy (quality of life at home above prolonging life in a nursing home) and staying with and taking care of your disabled child as long as possible, are important to a person, this conflict and/or trade off in these important values/life goals/core relationships can be discussed and translated into a fundamental goal. For example,
a fundamental goal could be to prolong life as long as possible, even with the chance of having to stay in a nursing home, provided that this person remains cognitively able to self-manage his or her life and that of his or her disabled child. In this sense, fundamental goals translate rather abstract elements such as values, acknowledging nuances and trade-offs in a certain context. Explicit awareness of all three goal levels and their interrelatedness is needed, although the emphasis on a certain type of goal in a specific care situation will be dependent on patient-specific, professional-specific and contextual factors. This three-goal model may provide a guide for CGS and the consideration of explicit goals in decision making with patients with multiple long-term conditions.

The three-goal model could be relevant for individualized management or care plans. In case of multimorbidity, a dynamic individualized care plan is recommended. Core elements of these plans are “optimizing quality of life, eliciting preferences and goals, weighing risks and benefits of implementing recommendations from single disease guidelines, addressing trade-offs, setting priorities, stopping potentially harmful or unnecessary medications and starting beneficial medications while simplifying regimens, integrating care, and minimizing treatment burden.” In individualized care plans, values are seen as guiding principles. Using the three-goal model in individualized care plans may be helpful to actually use values as guiding principles. In a process of fundamental goal-setting, values are translated into explicit fundamental goals, thereby also incorporating elements as personal history and core relationships. These explicit fundamental goals can be used as input for the elicitation of the other goal types. In this way, a goal-setting approach of different types of interrelated goals actually incorporates values into care plans and health-care decisions.

Berntsen et al. developed a goal typology with a distinction between professionally defined and personally defined goals. Personally defined goals are goals which “honor the patient’s right to make decisions about his/her personal matters”. Personal goals “amount to a personal construction of what ‘health’ means for the individual”. These personal goals are used to justify the choice of the goals a professional should pursue. Our three-goal model differs from Berntsen’s framework in two ways. Considering content, fundamental goals are based on and include values, aspects of personal history, individual priorities in quality of life and core relationships, thereby constituting a further elaboration on the concept of personal goals. Furthermore, in contrast to Berntsen et al, all types of goals are basically elicited jointly, although the weight of the patient’s and the professional’s input may vary for different types of goals. Although fundamental goals are very personal and can be difficult to construct, elicit and share, discussing and explicating these goals is a collaborative process between patient and practitioner. In our model, all types of goals are joint goals in this sense and not exclusively patient or professional goals.

It must be noted that fundamental goals and CGS show similarities with advance care planning (ACP). ACP is a formal decision-making process that aims to support patients in making decisions about future care in anticipation of the incapacity to make decisions due to a worsening condition. Patients consider the focus in health care on patient goals and values to be particularly helpful. ACP is usually part of an end-of-life care strategy and is used in the context of progressive illness and anticipated deterioration. In our view, discussing and explicating a patient’s fundamental goals and specifying values and underlying beliefs and preferences, could also be valuable in earlier stages of life, especially in patients with multimorbidity.

4.3 | Strengths and limitations

The methodological strengths of this study include the following: First, we worked with an interviewer who is trained as a GP, which may have encouraged the participants to speak frankly and directly from their own professional perspectives. The second coder has substantial experience in interview analysis but has no medical background, which helped us avoid a ‘medical’ bias in our data interpretation. Second, a purposive sampling and snowball extension method was used to recruit professional experts. In the Netherlands, both GPs and CGs deliver medical care to elderly people living independently, but they provide care in different settings. In this phase of theory development, we consider GPs and CGs to be complementary, as they both contribute to the saturation of data collection on current medical thinking on these themes. We are aware that our purposive sampling and snowball extension participant selection method has a risk of bias in the sense that the results cannot be generalized to the whole Dutch GP and CG population. However, although our selection of participants is not representative for the whole GP and CG population, these are representatives who can be considered specifically interested and busy in developing clinical practice, especially care for older patients, further. We considered recruitment of these professional experts a necessity to answer our research question, because a goal-oriented approach and CGS more specifically are not yet broadly implemented. Considering participants’ basic characteristics (Table 2); these show considerable variability and comparability in line with the actual Dutch context, for example in case of practice type.

A limitation of the study is that the categories in the theme “The consideration of fundamental goals” were based on data analysis of the answers spontaneously given by the clinicians. The clinicians in the first category, “No consideration of fundamental goals”, explicitly mentioned a primary focus on functional goals and/or disease-specific or symptom-specific goals. They did not mention setting nor taking the type of goals, we eventually labelled as fundamental goals into account. Based on our results, we cannot be sure that they never take fundamental goals into account in their daily patient care; however, we can conclude that fundamental goals were not their primary point of orientation, otherwise they would have mentioned (aspects of) fundamental goals. We did not ask this during the interview, because this would potentially influence the results.

A further limitation of the study is that the model was developed on the basis of practitioners’ perspectives. Evaluation and adaptation of the model on the basis of an analysis of patients’ and caregivers’ perspectives is a high priority area. In addition, the impact of eliciting fundamental goals on the quality of decision making and of care requires future research.
4.4 | Implications for practice and research

Further research on the patients’ perspectives on goals is required. Further combined theoretical and practice-based research on this topic of goal-orientation in the context of goal-setting and decision making could prepare a shift in clinical practice towards goal-oriented care for patients with multimorbidity.

5 | CONCLUSION

This qualitative study provides new insights into types of goals and the consideration of goals in care for elderly patients with multimorbidity. Based on the perspectives of clinicians, we expanded the concept of goal-oriented care by identifying a three-level goal hierarchy acting as a guide to clinical care of patients with multiple long-term conditions. Awareness of and application of explicit fundamental goals in addition to functional and symptom-specific and/or disease-specific goals could contribute in making daily care more patient goal-oriented. Future research is needed to refine and validate the developed three-goal model and to provide recommendations for medical training and practice.

<td>7. Participant knowledge of the interviewer</td>
<td>Former general practitioner. Interviews belonging to PhD research.</td>
<td></td>
</tr>
<tr>
<td>8. Interviewer characteristics</td>
<td>She has a background as a GP and an affinity for geriatric care. Considering working with an interviewer who is trained as a GP may have encouraged the participants to speak frankly and directly from their own professional perspectives. The second coder has substantial experience in interview analysis but has no medical background, which helped us avoid a 'medical' bias in our data interpretation.</td>

<td>Sampling</td>
<td>A purposive and snowball method aiming to recruit professional pioneers.</td>
</tr>
<tr>
<td>11.</td>
<td>Method of approach</td>
<td>By email. Part of the recruitment of GPs took place at a broader meeting of GPs holding a specialization in geriatric care.</td>
</tr>
<tr>
<td>12.</td>
<td>Sample size</td>
<td>33 (18 clinical geriatricians and 15 general practitioners)</td>
</tr>
<tr>
<td>13.</td>
<td>Non-participation</td>
<td>The response rates of clinical geriatricians and general practitioners were 86% and 54% respectively. Of the 21 CGs approached, one CG refused and two CGs did not respond to the first and reminder emails. A total of 28 GPs were approached. There were 6 non-responders. 3 GPs responded positively, but did not respond to proposed dates. There were two drop-outs (the interview was cancelled and there was no rescheduling (i.e. no response to proposed dates)). Two GPs of the same practice chose one participant. Their lack of time was the main reason not to participate.</td>
</tr>
<tr>
<td></td>
<td><strong>Setting</strong></td>
<td></td>
</tr>
<tr>
<td>14.</td>
<td>Setting of data collection</td>
<td>Five interviews were face-to-face, the others were held by telephone, as the medical practitioners’ busy schedules and varying locations required flexibility. The face-to-face interviews were held at the interviewee’s office.</td>
