Summary: Syndactyly is a congenital condition characterized by fusion of the fingers. If not treated correctly during infancy, syndactyly may hinder the normal development of hand function. Many surgical techniques have been developed, with the main goal to create a functional hand with the smallest number of operative corrections. Therefore, exact preoperative planning of the reconstructive procedure is essential. An imaging method commonly used for preoperative planning is 3-dimensional (3D) surface imaging. The goal of this study was to implement the use of this technique in hand surgery, by designing a virtual planning tool for a desyndactylyzation procedure based on 3D hand images. A 3D image of a silicon syndactyl model was made on which the incision pattern was virtually designed. A surgical template of this pattern was printed, placed onto the silicon model and delineated. The accuracy of the transfer from the virtual delineation toward the real delineation was calculated, resulting in a mean difference of 0.82 mm. This first step indicates that by using 3D images, a virtual incision pattern can be created and transferred back onto the patient successfully in an easy and accurate way by using a template. Thereafter, 3D hand images of 3 syndactyly patients were made, and individual virtual incision patterns were created. Each pattern was transferred onto the patient by using a 3D printed template. The resulting incision pattern needed minor modifications by the surgeon before the surgery was performed. Further research and validation are necessary to develop the virtual planning of desyndactylyzation procedures. (Plast Reconstr Surg Glob Open 2018;6:e1694; doi: 10.1097/GOX.0000000000001694; Published online 12 March 2018.)

INTRODUCTION

Three-dimensional (3D) stereophotogrammetry imaging was recently introduced into the hand surgery field. The advantages of this technique are its lack of radiation, cost-effectiveness, and good patient tolerance. It allows for accurate, immediately available 3D soft-tissue hand images.

To demonstrate its usefulness in clinical practice, we used 3D hand images during the preoperative planning process of a desyndactylyzation procedure. Syndactyly is a congenital abnormality, in which the fingers are fused. Preoperative evaluation of the soft and bony tissue elements in the syndactylized hand is necessary in every patient and done using conventional radiology images and computed tomography (CT) scan images. Hynes et al. found that CT angiographically guided release of adjacent webspaces benefits the patient. However, CT imaging has numerous disadvantages, like radiation, costs, and need for anesthesia when used for children. Until now, no harmless imaging technique exists that evaluates the soft tissues in a 3D method. The goal of this study was to implement the use of 3D stereophotogrammetry in hand surgery, by designing a method to virtually plan the incision pattern for a desyndactylyzation procedure and transfer this planning onto the patient.

SUBJECTS AND METHODS

A 3D image of an adult subject was made to simulate syndactyly and scaled down to an average toddler size. hand. This was used as a reference to create a silicon syndactyly model, and a new 3D image of this model was created. All images were obtained with the 3dMD cranial system (3dMD cranial system, Atlanta, Ga.), which consists of 5 pods with a total of 15 cameras. The obtained 3D image was loaded into 3ds Max 2016 (Autodesk Inc, San Rafael, Calif.). Thereafter, the incision pattern was virtually planned on the dorsal side by an experienced hand surgeon (T.W.) in 3ds Max (Fig. 1). Using a transparent filter setting of the model, the surgeon was able to plan the palmar side using the dorsal side as a reference (Fig. 2). To transfer the virtual planning to the silicon model, a patient-specific surgical template was designed and printed using the Laser-Sinter-System EOS P 396 3D printer (Oceanz, Ede, Netherlands). This template could then be placed exactly onto the silicon syndactyly model (Fig. 3), after which the planning could be marked with a marker pen. To evaluate the transfer of the virtual planning onto the model, another 3D image of this model with the markings was obtained. This image was loaded into Maxilim (Medicim, Leuven, Belgium) and matched with the virtual planning using an Iterative Closest Point algorithm. Thereafter, landmarks were placed at the corners of the virtually planned and real delineation to calculate the accuracy. Next, 3D images of 3 patients (2 male, 1 female, average age, 3.2 years) were obtained, and a virtual incision pattern was planned by the surgeon (T.W.). This planning was transferred onto the patient preoperatively. Postoperatively, the experiences of the surgeon using this template were obtained.

**RESULTS**

The virtual planning process was simple to perform, because the model could be viewed from any possible an-

The computer program for future delineations. The ex-
plate, resulting in broader markings on the patient than
ning, minor modifications were necessary due to the
avoided, leading to less scarring.

Furthermore, when the amount of necessary skin can be
calculated preoperatively, excessive skin grafting will be
avoided, leading to less scarring.

With this first use of 3D images in preoperative plan-
ing, minor modifications were necessary due to the
somewhat wide opening of the delineation in the tem-
plate, resulting in broader markings on the patient than
normally used. This was corrected preoperatively, and in
the computer program for future delineations. The ex-
periences of the hand surgeon proved the usage of the
template to be easy and to simplify the surgical procedure,
which will be helpful for less experienced surgeons or resi-
dents performing desyndactylization procedures.

In this study, we show an easy method for preoperative
hand surgery planning based on 3D images. This first step
proves that by using 3D hand images, a virtual incision pat-
tern can be created and transferred back onto the patient
successfully. The preoperative planning will reduce total
surgery time, as the surgeon can directly copy the incision
pattern from the template. The quality and therewith final
result of the incision pattern will be improved, as different
incisions and their results can be tested virtually, to reach
the optimal, individual incision pattern. With our future
research, we will continue to develop the virtual planning
tool for desyndactylization procedures, therewith expand-
ing the implementation of 3D imaging in hand surgery.

DISCUSSION

Syndactyly is 1 of the most common congenital disor-
der of the limbs, in which normal hand development may
be hindered when not treated in a timely manner. The
basic principles of the desyndactylization procedure have
been widely established.5–9 To reach the goal of creating
a functional hand, every surgical procedure aims to pro-
duce a deep and wide webspace with as little as necessary
skin grafting. 3D stereophotogrammetry is an easy to use,
safe imaging technique,10,11 which has proven to be a valid
method for capturing surface information and calculating
volume deficits.2,10,12 By using 3D images for exact plan-
ing, creating a deep webspace could be easier and therewith
distal migration of the web, could be avoided and therewith
distal migration of the web, could be avoided, leading to less scarring.

With this first use of 3D images in preoperative plan-
ing, minor modifications were necessary due to the
somewhat wide opening of the delineation in the tem-
plate, resulting in broader markings on the patient than
normally used. This was corrected preoperatively, and in
the computer program for future delineations. The ex-
