8 **Abstract** The Cellular Potts Model (CPM) is a powerful *in silico* method for simulating biological  
9 processes at tissue scale. Their inherently graphical nature makes CPMs very accessible in theory,  
10 but in practice, they are mostly implemented in specialised frameworks users need to master  
11 before they can run simulations. We here present Artistoo (Artificial Tissue Toolbox), a JavaScript  
12 library for building “explorable” CPM simulations where viewers can change parameters  
13 interactively, exploring their effects in real time. Simulations run directly in the web browser and do  
14 not require third-party software, plugins, or back-end servers. The JavaScript implementation  
15 imposes no major performance loss compared to frameworks written in C++; Artistoo remains  
16 sufficiently fast for interactive, real time simulations. Artistoo provides an opportunity to unlock  
17 CPM models for a broader audience: Interactive simulations can be shared via a URL in a  
18 *zero-install* setting. We discuss applications in CPM research, science dissemination, open science,  
19 and education.

---

## 21 Introduction

22 A growing community of computational biologists uses simulation models to reason about com-  
23 plex processes in biological systems. The Cellular Potts Model (CPM, **Box 1**) is a well-established  
24 framework for simulating interacting cells. Originally proposed as a model for cell sorting (**Graner**  
25 **and Glazier, 1992**), the CPM has since been extended with a plethora of biological processes such  
26 as proliferation, apoptosis, cell motion, and chemotaxis — allowing CPM users to model diverse  
27 phenomena ranging from slime mould formation to blood vessel development, tumour growth,  
28 and cell migration (**Marée et al., 2007; Szabó and Merks, 2013; Hirashima et al., 2017**).

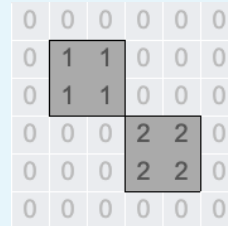

29 Nowadays, several mature modelling frameworks with CPM implementations exist, such as  
30 CompuCell3D (**Swat et al., 2012**), Morpheus (**Starruß et al., 2014**), Tissue Simulation Toolkit (**Daub**  
31 **and Merks, 2015**), and CHASTE (**Mirams et al., 2013**). Although CPMs are relatively efficient models,  
32 tissue-scale simulations still require substantial computational resources. For this reason, all of the  
33 abovementioned frameworks rely on the C++ programming language for computation steps, which  
34 requires them to be built for and installed on the user’s native operating system.

35 Here, we present “Artistoo” (Artificial Tissue Toolbox), a CPM framework built entirely in JavaScript.  
36 Although interpreted languages like JavaScript have classically been deemed too inefficient for  
37 running simulations, we found that this no longer holds: investments by major tech companies  
38 have tremendously improved JavaScript engines over the past years, to the point that our CPM now  
39 has no major performance disadvantage compared to existing C++ frameworks.

40 The JavaScript implementation of Artistoo opens up new possibilities for rapid and low-barrier

### Box 1. Cellular Potts Models

Cellular Potts Models (CPMs) model cells and tissues as collections of pixels on a 2D or 3D grid, where each pixel has an “identity” linking it to a specific cell or to the empty background:

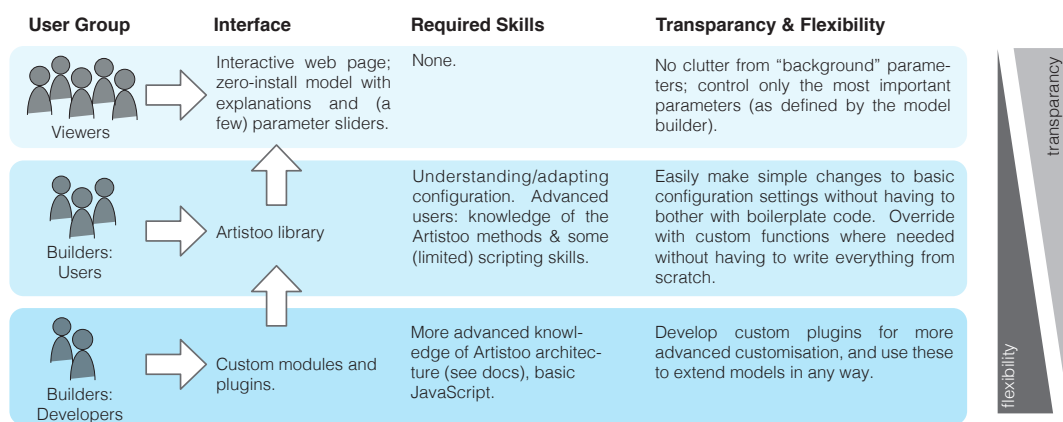

**Box 1 Figure 1.** An example CPM grid with pixels belonging to the background (identity 0) or to one of two cells (identities 1 and 2).

Model dynamics arise from stochastic attempts to change these identities, for which the success rate  $P_{\text{change}}$  is linked to the system's *global energy* or *Hamiltonian*,  $H$ . The energetic effect  $\Delta H$  of the proposed change determines  $P_{\text{change}}$ : energetically favourable changes ( $\Delta H < 0$ ) always succeed, while the success rate of unfavourable changes ( $\Delta H > 0$ ) decays with the energetic “cost”:  $P_{\text{change}} = e^{-\Delta H/T}$ . Here, the “temperature”  $T$  is a model parameter controlling noise: a higher  $T$  allows more energetically unfavourable changes to succeed.

CPM dynamics are thus controlled by the Hamiltonian  $H$ , an energy function defined by the modeller.  $H$  can contain multiple terms to represent different biophysical processes, such as adhesion (interface energies) and shape elasticity (energetic penalties for cells stretching or compressing beyond a given size). One of the CPM's strengths is that almost any desired behaviour can be encoded into the model, provided that the modeller can come up with a suitable energy term. Furthermore, model energies can be linked to other equations (e.g. diffusion of some signalling molecule), allowing even more flexibility in the processes a CPM can simulate. For further details on typical energy functions and model dynamics, we refer the reader to *Interactive Simulation 1* in *Appendix 1*.

As pixels can only have one cell identity at the same time, the property of *volume exclusion* emerges naturally in the model. This allows cells to interact with each other automatically. This — together with its flexibility and ability to capture detailed cell shapes — has made the CPM a popular tool for modelling cell-cell interactions and the resulting tissue dynamics (*Marée et al., 2007; Szabó and Merks, 2013; Hirashima et al., 2017*).

Nevertheless, like any model, CPMs have their limitations. For example, criticisms have included their lack of scalability, as well as difficulties in linking CPM parameters to measurable, real-world quantities. We note that ongoing developments in the field are addressing some of these concerns; for details on CPM strengths and limitations (and efforts to overcome these), we refer the reader elsewhere (*Tapia and D'Souza, 2011; Liedekerke et al., 2015; Magno et al., 2015; Rens and Edelstein-Keshet, 2019; Buttenschön and Edelstein-Keshet, 2020*).

**Figure 1.** Artistoo provides different levels of access depending on the audience.

74 sharing of CPM simulations with students, collaborators, and readers or reviewers of a paper. Unlike  
 75 existing frameworks, Artistoo allows building simulations that run in the web browser without the  
 76 need to install any software: Artistoo models run on any platform providing a standards-compliant  
 77 web browser — be it a desktop computer, a tablet, or a mobile phone. These simulations can  
 78 be published on any web server or saved locally and do not rely on any back-end servers being  
 79 available. They can be made explorable, enabling viewers to interact with the simulation and see  
 80 the effect of changing model parameters in real-time.

81 In this paper, we will first briefly explain the key design principles behind Artistoo. We will then  
 82 highlight applications in teaching, research, science dissemination, and open science where we  
 83 envision that the zero-install, web-based architecture of our framework could be particularly useful.

## 84 Results

### 85 Implementation

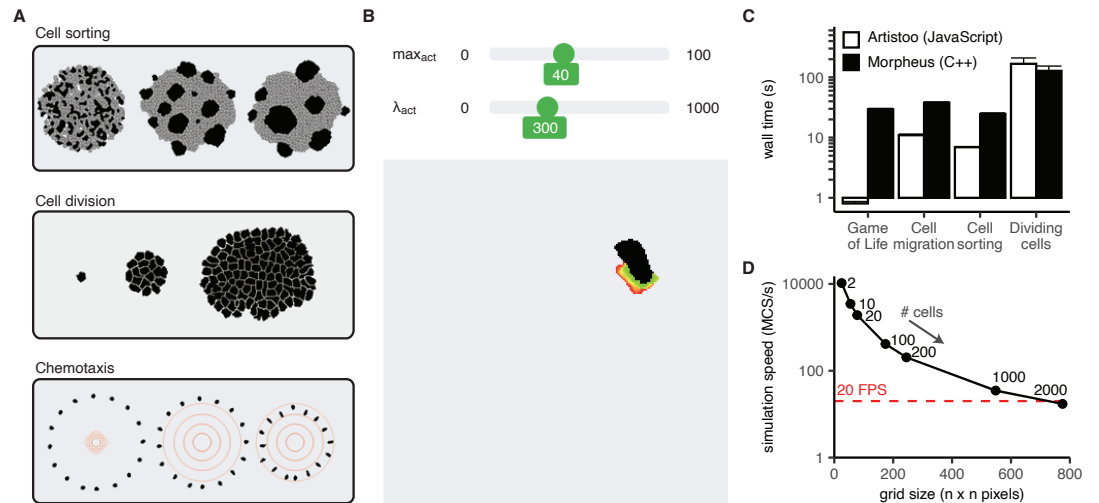

86 Artistoo is a JavaScript library implemented as an ECMAScript 6 module, which can be loaded  
 87 into an HTML page or accessed from within a Node.js command line application. Artistoo is an  
 88 open-source library released under the MIT license, and is freely available on GitHub at <https://github.com/ingewortel/artistoo>.  
 89

### 90 Design philosophy

91 Computational modelling research involves two important, but distinct categories of researchers  
 92 that tend to have different types of expertise. On the one hand, there are the model *builders*, the  
 93 scientists designing the models and performing the research; these are typically computational  
 94 biologists with at least some basic programming skills. On the other hand, there are the model  
 95 *viewers*, members of the broader research community who should be able to access and understand  
 96 these models once they are built; this group may also include biologists and students without  
 97 programming expertise.

98 A major challenge in the design of modelling software is to cater to both these groups at the  
 99 same time. Tools revolving around a front-end graphical user interface are ideal for viewers (no  
 100 programming required), but tend to lose some of the flexibility desired by builders (anything not yet  
 101 implemented in the GUI typically becomes harder to do, and it becomes more difficult to automate  
 102 simulations and post-processing). Vice versa, a more flexible coding-based tool is comfortable for  
 103 builders but rapidly becomes inaccessible for most viewers.

104 The implementation in JavaScript allows Artistoo to resolve this problem by presenting each  
 105 user group with a different interface (**Figure 1**). Model *viewers* access an HTML page provided by the  
 106 model builder, which contains a model visualisation and interactive access to the most important

**Figure 2.** (a) Artistoo supports simulation of diverse biological processes; (b) users can interact with browser-based simulations via sliders, in real-time. (c) Artistoo performance is comparable to that of the Morpheus framework. Data show wall times (mean+SD of 5 runs) for four CPM models implemented in both frameworks (see Materials and Methods for implementation details). (d) Scalability of the cell sorting simulation; simulation speed in Monte Carlo Steps per second (MCS/s) for different grid sizes (mean $\pm$ SD of 5 runs). Red line indicates 20 frames per second, a minimum speed required for a "real-time" simulation for the human visual system. See also **Appendix 1** for interactive versions of the simulations shown in panels b-d. Artistoo Node.js scripts for the simulations in panels c,d are available on GitHub (**Wortel and Textor, 2020**).

**Figure 2-Figure supplement 1.** Alternative representation of **Figure 2d** showing scaling with domain size

107 parameters (improving transparency because viewers are not distracted by an overload of options  
 108 they do not need). Such HTML pages are accessible in a zero-install setting, explorable via parameter  
 109 sliders, and remain highly accessible: no knowledge of the Artistoo framework or model details is  
 110 required for viewers to operate them.

111 Model *builders* create these web applications using the Artistoo framework. They can do this at  
 112 different levels of complexity: Artistoo *users* build models via simple changes to configuration objects  
 113 (requiring very little knowledge of Artistoo or programming), or by incorporating the many available  
 114 methods in a few simple lines of code; this requires no in-depth knowledge of the framework  
 115 "under the hood" architecture while still providing high flexibility. Finally, Artistoo *developers* have  
 116 the ultimate freedom to add custom plugins to the existing framework where needed. Only this  
 117 group requires in-depth knowledge of the framework and slightly more advanced JavaScript skills.  
 118 The online documentation at <https://artistoo.net/> helps both these groups to get started with the  
 119 framework.

## 120 Approachability

121 The methods currently implemented in the framework allow users to simulate, visualise, and  
 122 analyze a wide range of CPM models (**Figure 2A**). Our Github repository contains example code  
 123 for models of various biological processes (e.g. simulations of tissues, cell migration, and cell  
 124 interactions). First-time users can download these HTML pages and modify parameters without  
 125 needing to learn the implementation details of the framework, or to have programmed in JavaScript  
 126 before. Alternatively, the `Simulation` class provides default methods for setting up and visualising  
 127 simulations, allowing users to get started with the library without having to set up this "boilerplate"  
 128 code themselves. Advanced users can instead build simulations from scratch and customise  
 129 them using the many available options and methods. Once they become accustomed with the  
 130 framework, they can also develop and plug in their own code modules (see "Modularity and  
 131 flexibility" below). An example interactive HTML simulation (**Figure 2B**) is included in **Appendix 1**,

132 **Interactive Simulation 2.** Full documentation as well as a user manual with step-by-step tutorials  
133 are available at <https://artistoo.net/>.

#### 134 Modularity and flexibility

135 A typical CPM simulation consists of different types of components: the grid on which cells are  
136 simulated, the energy rules governing cell behaviour in the model, separate processes such as cell  
137 proliferation or diffusion, and the visualisation and quantification methods used to produce outputs.  
138 A key strength of the CPM is that it can be easily extended with custom terms to model specific  
139 processes. To facilitate such customisation, we have set up the code in a highly modular fashion.  
140 These modules can be combined freely to build a custom simulation. In addition, developers can  
141 supply their own custom modules — containing any of the aforementioned simulation components  
142 — to integrate with the framework and to share with other users.

#### 143 Performance and scalability

144 Although maximal performance is not a design goal of our framework *per se*, Artistoo should not be  
145 much slower than comparable frameworks either: running explorable simulations in real-time is only  
146 feasible if computations are reasonably efficient. Indeed, we implemented various simulations both  
147 in Artistoo and in Morpheus and found that both frameworks had similar performance (**Figure 2C**).  
148 In fact, Artistoo was slightly faster in all but one of these examples, although differences tended to  
149 be small; even in the case where Artistoo was slower (cell division), the difference in performance  
150 was not so large that real-time browser simulations became infeasible. Simulation speed scales  
151 linearly with the total number of pixels on the grid and does decrease for very large systems, but  
152 real-time simulations remain feasible for a reasonable range of grid sizes (**Figure Supplement 1**,  
153 **Figure 2D**). This would allow sharing of at least a reasonable prototype of larger-scale models.

#### 154 Portability

155 To make Artistoo more accessible for users familiar with other frameworks, we have built a prototype  
156 for an online tool that converts Morpheus model files into Artistoo code ([https://artistoo.net/  
157 converter.html](https://artistoo.net/converter.html)). In some cases, models may not (yet) be fully portable due to differences in the  
158 types of models supported; in that case, the tool returns the closest possible analogue and logs any  
159 changes it had to make, providing suggestions to help users further. This tool offers a starting point  
160 for any users who wish to build Artistoo web applications from their existing models. A similar tool  
161 converts Artistoo models to Morpheus XML, allowing users to continue in another framework (e.g.  
162 for upscaling models, multiscale models, etc).

### 163 Applications

164 We here highlight a number of settings where Artistoo might complement other available modelling  
165 frameworks, focusing on the unique feature of Artistoo: it allows users to build and share explorable  
166 simulations in a *zero-install* setting. We discuss how this opens up novel opportunities of sharing  
167 CPM-based research and provide examples from our own work.

#### 168 Teaching

169 When organising practical computer work in the context of classroom teaching, getting software to  
170 work on every student's computer can consume a substantial amount of time and effort. Especially  
171 when teaching large classes in limited time, installing an entirely new modelling framework for  
172 a single course assignment may not be appropriate. The *zero-install* feature of Artistoo might  
173 therefore be attractive for use of CPM modelling in the classroom. We frequently use the framework  
174 in teaching and found it feasible to let students run and understand CPM models in a workshop  
175 of just a few hours — even when students had no programming experience and were given just  
176 a single lecture on the CPM in advance. We provide an introductory assignment on the CPM in  
177 **Application 1** in **Appendix 2**, which readers may use and adapt freely for their own courses, and  
178 refer to **Interactive Simulation 1** in **Appendix 1** for an interactive tutorial on the CPM.

179 **Communication and Open Science**

180 While the move towards open science has prompted many to share their code with publications,  
 181 understanding and using this code often remains challenging for readers who do not use similar  
 182 models themselves. We envision that by sharing interactive Artistoo simulations via a simple URL,  
 183 computational biologists can make their modelling research more accessible for the readers and  
 184 reviewers of their papers; if readers can interact with model parameters themselves without the  
 185 barrier of having to install special software, this may greatly improve the transparency of CPM  
 186 research. This would allow others to evaluate these models more critically, as well as foster the  
 187 exchange of ideas between scientists from different disciplines.

188 In addition, interactive simulations can help communicate CPM-based science at conferences  
 189 or in classrooms. We frequently use the framework `reveal.js` (*Hattab and contributors, 2020*)  
 190 to build slideshows in HTML, in which live, interactive Artistoo demonstrations help explain how  
 191 models work. Similarly, interactive simulations can be shared on a conference poster via a QR code,  
 192 which other attendees can explore on their mobile phone. We provide examples of both in the  
 193 Supplementary Materials (*Application 2, Application 3* in *Appendix 2*).

194 **Research and Collaboration**

195 Although the CPM is extremely flexible in the types of behaviours it can model, it can be difficult  
 196 to find the parameter ranges where these behaviours occur. We found that an interactive web  
 197 page with instantaneous feedback, where the effect of changing parameters is visible in real-  
 198 time (*Figure 2* and *Interactive Simulation 7* in *Appendix 1*), can substantially speed up parameter  
 199 selection. This visual approach also picks up on unpredicted behaviours and artefacts (e.g. cell  
 200 breaking) that are difficult to detect from numerical outputs alone. Moreover, we note that sharing  
 201 these interactive pages allows us to tune parameters in collaboration with experimental biologists,  
 202 helping us improve our models at an early stage. Thus, building a web-based prototype of a  
 203 simulation can speed up parameter tuning and help obtain higher quality models.

204 Once a web-based prototype has been built and tuned, it can easily be ported to the Node.js  
 205 JavaScript interpreter. This allows users to run a simulation as a command line application and  
 206 store any desired simulation output locally. The resulting images or statistics can then be opened  
 207 in other programs for further postprocessing, as demonstrated by two examples (*Application 4* in  
 208 *Appendix 2*).

209 **Discussion**

210 The recent rise of the open science movement has changed the way research outputs are being  
 211 shared and communicated. This may be especially important for computational models, which have  
 212 classically been difficult to share because of the required software and coding skills. Transparent  
 213 model sharing calls for new strategies to make models accessible for broader audiences.

214 Indeed, several such efforts have been made in recent years. The CPM framework CompuCell3D  
 215 now hosts an online version on NanoHub, which users can access without installing software  
 216 locally (*Gianlupi and Sego, 2021*). Beyond the CPM field, modelling frameworks like Tellurium (*Choi*  
 217 *et al., 2018*) and PhysiCell (*Ghaffarizadeh et al., 2018*) have also created online access through  
 218 NanoHub; these frameworks have also shown how such online models can be made interactive  
 219 by using (variations of) Jupyter notebooks (see, for example, *Macklin and Heiland (2020); Medley*  
 220 *et al. (2018); Somogyi (2019)*). The potential of explorable online web pages in communication and  
 221 teaching is also demonstrated by the emerging practice to share R models in the form of Shiny  
 222 apps (*Schönbrodt, 2014; Zehetleitner and Schönbrodt, 2015; Granjon, 2019*). And finally, the online  
 223 collection of “complexity explorables” (*Brockmann, 2020*) is a fantastic example of how to combine  
 224 interactive online simulations with explanatory text to communicate modelling research.

225 With Artistoo, we now hope to open up this powerful avenue of model sharing for CPM research,  
 226 allowing users to build online web pages and “explorables” that combine interactive simulations  
 227 with model explanations. We here show that the framework’s performance (similar to that of

228 existing frameworks in C++) is sufficient to allow for interactive CPM simulations. We have been  
 229 developing the library for more than five years, also using it for robust simulation work in our  
 230 research; see, for example, (*Wortel et al., 2020*). We are continuing to develop the library for our  
 231 own work, and welcome suggestions and code contributions from the community.

232 We do not envision Artistoo to *replace* existing modelling software; rather, it can complement  
 233 software directed at computational biologists and developers by letting users build explorable and  
 234 sharable versions of a simulation. To facilitate this process, we have built a (prototype) tool to help  
 235 users convert models between different frameworks (currently: Artistoo and Morpheus). Although  
 236 Artistoo already offers a wide range of methods, it does not (yet) support all features of existing  
 237 frameworks (Morpheus, CHASTE, CompuCell3D, Tissue Simulation Toolkit), such as solvers for  
 238 reaction-diffusion equations or SBML-encoded intracellular signalling, or writing output in formats  
 239 like VTK and HDF5. Nevertheless, Artistoo simulations are highly customisable, and a wide range of  
 240 CPM models can already be constructed using the framework in its current state. The software's  
 241 modular structure also makes it easy for future developers to extend it with custom code.

242 In summary, to the best of our knowledge, Artistoo is the first CPM simulation framework  
 243 supporting interactive simulations in the web browser that can be shared via a simple URL, without  
 244 requiring installed software or back-end servers. We hope that this will unlock avenues of sharing  
 245 and communicating (CPM) simulations to much larger audiences.

## 246 Methods

Key resources table

Reagent type (species) or resource	Designation	Source or reference	Identifiers	Additional information
Software, algorithm	Morpheus	Publication ( <i>Starruß et al., 2014</i> )	RRID:SCR_014975	version 2.1.0
Software, algorithm	Artistoo	This paper, see also <a href="https://artistoo.net">https://artistoo.net</a>	RRID:SCR_020983	version 1.0.0

247 This section contains implementation details of the simulations used to assess Artistoo (v1.0.0)  
 248 performance. All simulations were run in the console mode (using Node.js, which contains the  
 249 same JavaScript engine as the Chrome web browser). All Artistoo code is available in the repository  
 250 <https://github.com/ingewortel/artistoo-supplements/> (*Wortel and Textor, 2020*), as are interactive  
 251 HTML versions of each simulation. Please visit <https://ingewortel.github.io/artistoo-supplements/>  
 252 for a web interface to access interactive simulations online. We refer to the provided code for  
 253 details of the implementation, but summarise the most important settings here.

## 254 Framework comparisons

255 To compare performance of Artistoo versus that of Morpheus (v2.1.0), we performed 4 different  
 256 simulations in both frameworks. For this, we used the default examples provided with Morpheus,  
 257 and rebuilt similar simulations in Artistoo.

### 258 Game of Life

259 This is an implementation of the Game of Life, a Cellular Automaton (CA) of John Conway (see  
 260 also *Interactive Simulation 3* in *Appendix 1*). The simulation was run on a 50 x 50 pixel grid with  
 261 random initial conditions. The simulation was run for 500 steps, storing a PNG image every 20  
 262 steps. This simulation is the Morpheus example *Miscellaneous/GameOfLife.xml* (version 4).

### 263 Protrusion model

264 This model of a migrating cell implements an actin-inspired migration model (*Niculescu et al.,*  
 265 **2015**) (see also *Interactive Simulation 4* in *Appendix 1*). A single cell was seeded in the middle  
 266 of a 200 x 200 pixel grid. Two obstacles of radius 10 were placed at a distance of 50 pixels to  
 267 the left and right of the cell, respectively. Simulations were run for 15,000 MCS, logging the cell's  
 268 centroid every 10 MCS and saving a PNG every 250 MCS. This simulation is the Morpheus example  
 269 *CPM/Protrusion\_2D.xml* (version 4).

### 270 Cell sorting

271 This simulation implements the classical CPM model published by Graner and Glazier (*Graner and*  
 272 **Glazier, 1992**) (see also *Interactive Simulation 5* in *Appendix 1*). 50 cells each of two cell types were  
 273 seeded on a 200 x 200 pixel grid within a circle of radius 67 from the grid midpoint. Simulations  
 274 were run for 2000 MCS, logging statistics every 10 MCS and saving a PNG every 100 MCS. This  
 275 simulation is the Morpheus example *CPM/CellSorting\_2D.xml* (version 4), where the *StopTime* field  
 276 was changed from 2.5e4 to 2000.

### 277 Cell division

278 A CPM linked to cell division (see also *Interactive Simulation 6* in *Appendix 1*) was simulated on a  
 279 500 x 500 pixel grid. The grid was initialised with 20 cells in a circle of radius 35 surrounding the grid  
 280 midpoint. Simulations were run for 40,000 MCS, logging the number of cells every 100 MCS and  
 281 saving a PNG every 1000 MCS. This simulation is the Morpheus example *CPM/Proliferation\_2D.xml*  
 282 (version 4).

### 283 Scalability of cell sorting

284 For the scalability simulations, simulations were run without outputting images. This allowed us  
 285 to investigate the simulation speed separately from the time it takes to draw the entire grid. Note  
 286 that if the drawing step becomes a limiting factor for running the simulation, it is always possible to  
 287 speed up the process by drawing only once every few steps, or by choosing a more efficient drawing  
 288 method (e.g. drawing only cell borders rather than entire cells).

289 Simulations contained 1, 5, 10, 50, 100, 500, or 1000 cells per cell type. The grid dimensions  
 290 were adaptively scaled such that  $x = y = \sqrt{1.5P_{\text{tot}}}$ , with  $P_{\text{tot}}$  the total number of pixels of all the cells.  
 291 Cells were seeded within a radius  $0.8\sqrt{P_{\text{tot}}/\pi}$  from the grid midpoint. Other settings were the same  
 292 as in the cell sorting simulation described under *Framework comparisons*.

### 293 Acknowledgments

294 The authors thank Nino van Halem and Ankur Ankan for their contributions to the code, Peter  
 295 Linders for valuable feedback on an early version of the Artistoo manual, and Franka Buytenhuijs  
 296 for thoroughly checking the interactive explorables.

### 297 Funding

298 This work was supported by KWF Kankerbestrijding [10620 to J.T.], a Vidi grant from NWO [192.084  
 299 to J.T.], and a PhD grant by the Radboudumc [to I.W.].

362 **Appendix 1**363 **Interactive Simulations**

364 To showcase how interactive simulations can be used in teaching and communication,  
365 we have prepared a number of "interactive simulations" and "explorables". These explain  
366 the CPM framework and the models used in *Figure 2*, and will also be made available on  
367 <http://artistoo.net> later.

368 All simulations described below are available on Github at [https://github.com/ingewortel/](https://github.com/ingewortel/artistoo-supplements)  
369 [artistoo-supplements](https://github.com/ingewortel/artistoo-supplements) (*Wortel and Textor, 2020*), which also contains instructions on how to  
370 use these files from your computer. For easy access, interactive simulations and applications  
371 are also accessible directly via <https://ingewortel.github.io/artistoo-supplements/>.

372 **Interactive Simulation 1.** This explorable explains the algorithm and dynamics behind the CPM for  
373 readers unfamiliar with this type of model.

374 **Interactive Simulation 2.** This explorable describes a CPM extension that lets cells migrate actively  
375 (*Niculescu et al., 2015*), as depicted in *Figure 2b*.

376 **Interactive Simulation 3.** This explorable describes a famous Cellular Automaton (CA) model called  
377 the "Game of Life"; the classic model by John Conway that is also mentioned in *Figure 2c*.

378 **Interactive Simulation 4.** Interactive version of the "Cell migration" simulation in *Figure 2c*. This  
379 model once again depicts a migrating cell as defined in (*Niculescu et al., 2015*) (see also *Interactive*  
380 *Simulation 2* for the full "explorable" with an explanation of the model).

381 **Interactive Simulation 5.** Interactive version of the "Cell sorting" simulation in *Figure 2c*. This classic  
382 model was the first CPM as developed by Graner and Glazier (*Graner and Glazier, 1992*). Two  
383 populations of cells spontaneously sort themselves.

384 **Interactive Simulation 6.** Interactive version of the "Dividing cells" simulation in *Figure 2c*; the  
385 explorable shows what happens when we couple division dynamics to the spatial information in a CPM.

386 **Interactive Simulation 7.** Interactive simulation of "collective migration". This simulation is an  
387 extension of *Interactive Simulation 2*, but now contains more than one cell and allows users to tune  
388 more different CPM parameters. See also *Application 1* in *Appendix 2*. This simulation also serves as  
389 an example of how interactive CPM simulations can be used to tune parameters.

404 **Appendix 2**405 **Applications**

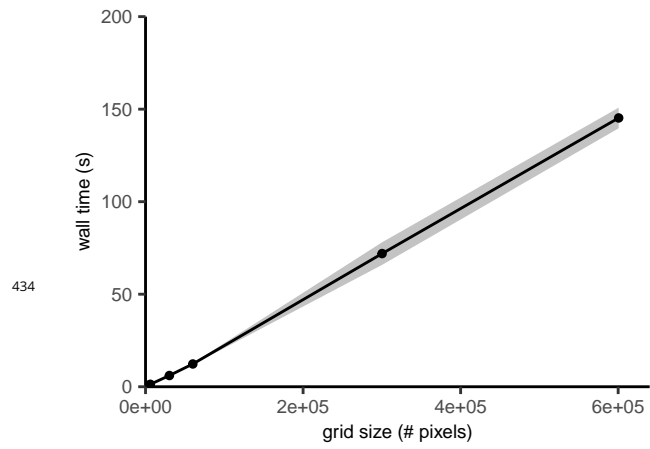

406 All applications described below are available on Github at [https://github.com/ingewortel/](https://github.com/ingewortel/artistoo-supplements)  
407 [artistoo-supplements](https://github.com/ingewortel/artistoo-supplements) (*Wortel and Textor, 2020*). For easy access, interactive simulations and  
408 applications are also accessible directly via <https://ingewortel.github.io/artistoo-supplements/>.

409 **Application 1.** An example exercise used to for teaching workshops on the CPM for beginning users.  
410 Readers are free to use this material in their own education. The file refers to an online simulation, but  
411 the same simulation is included as *Interactive Simulation 7* in *Appendix 1*.

414 **Application 2.** An example slideshow containing a live Artistoo simulation. The slides were built using  
415 the revealjs framework (*Hattab and contributors, 2020*), which allows users to build slidesets in HTML.

418 **Application 3.** A website accompanying a conference poster, which can be shared via a QR code on the  
419 poster itself. Please visit <https://computational-immunology.org/inge/poster-cpmjs/> to view this  
420 example.

423 **Application 4.** Two examples of how to use the Node.js version of Artistoo to export numeric outputs  
424 and images, and to process these for downstream analysis using other programs. Both are available  
425 from our Github repository at <https://github.com/ingewortel/artistoo-supplements> (*Wortel and Textor,*  
426 *2020*), see <https://github.com/ingewortel/artistoo-supplements/tree/master/applications> for usage  
427 instructions. The "analysing-data/" folder contains a simulation of diffusion (so not a CPM); to show its  
428 numerical accuracy, the downstream analysis in R compares simulation output to an analytical solution.  
429 The "making-movies/" folder contains a simulation of a migrating cell, and shows how to make an  
430 animated movie of the produced images. Numerical outputs are also stored and used in a downstream  
431 R script to produce a cell track and a mean squared displacement (MSD) curve.

**Figure 2-Figure supplement 1.** Different plot of the data from **Figure 2d** showing wall time (s) for the entire simulation of 2500 MCS at different domain sizes (mean $\pm$ SD of 5 runs); simulation duration scales linearly with the number of pixels on the grid.
