Abstract: The synthesis of various cyclic α-hydrazino esters is described. The key-step involves an intramolecular reaction of a highly reactive N-acylhydrazonium ion, leading to a cyclic cationic intermediate which either rearranges via an aziridinium ion, or leads to the unrearranged piperazic ester. A deprotection sequence that furnishes the free α-hydrazino acids is detailed.

INTRODUCTION

Since the first discovery three decades ago,1 various tetra- and hexahydro-3-pyridazinecarboxylic acids, or piperazic acids (Piz) have been isolated. As constituents of several biologically active peptides such as the cyclic peptides monamycin,2 L-156,6023 and luzopeptin A,4 the acyclic antrimycins,5 cirratiomycins,6 azinethricin antitumor antibiotics7 and the recently discovered antibiotic mathlystatin B,8 these compounds constitute a novel subclass of cyclic amino acids. Some of the piperazic acids present in these peptides are shown below.

The resemblance of these types of molecules with the corresponding α-amino acids suggests a promising potential as pharmacologically important compounds.9,10 Recently, several syntheses of cyclic hydrazino acids were reported among which piperazic acid 2 was synthesized via a hetero Diels-Alder reaction of a dienophile with an azo compound.11 Furthermore, the acids 1, 4 and 5 were obtained via intramolecular condensations of enantiopure 2-hydrazino-5-oxo-pentanoic esters,12-15 the latter being prepared by enantioselective α-amination of enolates with an azodicarboxylate.16

Herein, we wish to report a novel approach to the synthesis of (racemic) cyclic α-hydrazino acids, which extends our previously reported work on N-acetylhydrazonium ion cyclizations.17 For example, a sequence that is expected to lead to the chlorine substituted α-hydrazino acid 3 involves ring closure of 8 via the N-acetylhydrazonium ion 7 to the protected α-hydrazino acid 6 (eq 1).
Comparison with well-investigated N-acyliminium ion cyclizations leads to the expectation that the cationic intermediate 7 will adopt a chair-like conformation, in which the N-acyliminium part has a (Z)-geometry. The preference for this geometry can be understood by considering the two possible conformations A and B of the hydrazonium ion. The (E)-isomer B is likely to be less stable as a result of pseudo-pseudo-allylic 1,3-strain between the two carbonyl functions, which is absent in the (Z)-isomer A.

Attack of a nucleophile (e.g., chloride) on the intermediate π-complex of the olefin with the iminium ion will result in an overall trans-addition to the double bond, leading to the desired trans-relationship between the substituents in compound 6. The free hydrazine 3 might be obtained by deprotection of 6, in which R and R' are appropriate functional groups. The cyclization precursor 8 will be prepared from the suitably functionalized hydrazine 9 by alkylation with allyl bromide and methyl glyoxylate, respectively.

Moreover, introduction of various nucleophilic side chains will be shown to lead to the synthesis of numerous functionalized cyclic α-hydrazino acids of different ring sizes.

RESULTS AND DISCUSSION

The benzyl and allyloxyacarbonyl (Alloc)20 function were considered to be proper groups to functionalize both nitrogen atoms. In order to obtain the desired starting material 12, an excess of hydrazine hydrate was treated at -20 °C with allyl chloroformate to give allyl carbazate 10 (eq 2),21 which was readily purified by distillation. At lower temperatures, the reaction did not proceed whereas at higher temperatures the diacylated product was obtained. Because straightforward alkylation of 10 with benzyl chloride mainly led to dibenzylation of allyl carbazate (10), an alternative route was chosen for the synthesis of the monobenzyalted carbazate 12.

Thus, allyl carbazate (10) was condensed with benzaldehyde to give the hydrazone 11, which was reduced with NaBH₄-CN to give 12 as its cyanoborane complex.22 Hydrolysis of the complex with NaOH afforded the monobenzyalted carbazate 12. Distillation of 12 led to a dramatic decrease of the yield, so that crude 12 (virtually pure according to ¹H NMR data) was used for further reactions.

The functionalized hydrazine 12 was alkylated at the nucleophilic benzylic nitrogen atom with various halides as summarized in Table I (halide (1.1 equiv), K₂CO₃ (1.2 equiv), LIF (cat), butanone, acetone or ethanol, reflux). In general, reasonable to good yields were obtained for the activated halides. The less reactive butenyl bromide gave a lower yield (entry 8). Surprisingly, reaction of 12 with 4-iodo-1-(trimethylsilyl)-2-butyne under refluxing conditions led to desilylation of the propargylsilane moiety so that the allene 17 was
formed in a rather low yield (entry 7). At room temperature, however, the desired propargylsilane 21 was formed (entry 12). The (E)-vinylsilane 22 (entry 13) was obtained upon alkylation of 12 with (E)-3-bromo-1-(trimethylsilyl)-1-propene \(25,26\) while the 1:1.9 (E)/(Z) mixture of vinylsilanes 23 (entry 13) was obtained by alkylation of 12 with a 1:2.5 (E)/(Z)-mixture of 3-bromo-1-(trimethylsilyl)-1-propene.\(^{26-28}\)

Introduction of the glyoxylate moiety was performed by stirring the alkylation product in the presence of anhydrous methyl glyoxylate.\(^{29}\) The reaction rate of this condensation with glyoxylate proved to be strongly dependent on the steric bulk of the alkyl group. For example, the allyl precursor 13 (entry 1) reacted within 2 h to give the desired product, while for the benzyl precursor 19 (entry 9) a longer reaction time was required (up to 40 h). Because polymerization of unreacted methyl glyoxylate was a major side reaction, freshly distilled methyl glyoxylate had to be added after 18 h if the reaction was not completed. In some cases, large amounts (ca. 20 equiv) of methyl glyoxylate were used, so that purification by flash chromatography of the intermediate hydroxy compound was necessary. Acetylation (acetic anhydride (5 equiv), DMAP (cat), pyridine, rt) led to the cyclization precursors 24-34 in good yields as shown in Table I.

The cyclization reactions were carried out with the Lewis acids titanium tetrachloride (2 equiv, \(-78^\circ\mathrm{C}\rt),\) tin tetrachloride (2 equiv, \(-78^\circ\mathrm{C}\rt),\) diethylaluminum chloride (2-4 equiv, \(-78^\circ\mathrm{C}\rt),\) and boron trifluoride etherate (2-6 equiv, 0 \(^{\circ}\mathrm{C}\rt),\) and the protic acid formic acid (neat). The results are shown in Table I.

Cyclization of the allyl precursor 24 (entry 1) led to the unexpected formation of the five-membered rings 35 with the trans-isomer as the main product. These products cannot arise from a 'normal' 5-exo-type cyclization, because the chloromethyl substituent would then be at the 4-position. A possible explanation for the formation of 35 is detailed in eq 3. It has been shown that in corresponding N-acyliminium cyclizations,\(^{18}\) the cationic intermediate is already formed at \(-78^\circ\mathrm{C}\) and stabilized as a dioxycarbenium ion by the carbamate function (compare 53, eq 4). Quenching with saturated aqueous sodium bicarbonate at \(-78^\circ\mathrm{C}\) then gives the corresponding hydroxy compound. In the case of these hydrazonium ions, such a sequence might block the rearrangement and directly give the precursor 54 for the piperazic acid 2. However, when the cyclization reaction of 24 was quenched with saturated aqueous sodium bicarbonate at \(-78^\circ\mathrm{C}\) or at \(-30^\circ\mathrm{C}\), only starting material was recovered. Apparently, formation of the \(N\)-acylhydrazonium ion is more difficult than of its iminium analog. Reaction only took place at \(-20^\circ\mathrm{C}\) (according to TLC), but quenching after stirring for 30 min at this temperature afforded a mixture of starting material and the rearranged products 35. This probably means that as soon as the intermediate cationic six-membered ring 50 (\(R = H\)) is formed, stabilization via the aziridinium intermediate 51 (\(R = H\)) takes place so that stabilization via the dioxycarbenium ion 53 does not occur.

a) The (E)/(Z)-ratio could not be determined from the 1H NMR spectrum. b) Yield in one step from allylbisazate (14).

The formation of the trans-five-membered ring was confirmed by reduction of the trans-cyclization product 35 with tri-n-butyltin hydride to give 56 (Chart 1), clearly showing the characteristic doublet of the methyl substituent in the 1H NMR spectrum (0.98 ppm, d, J = 7.1 Hz). The structure was further proven by an X-ray crystallographic analysis of the deprotected product 66 (Fig I). The formation of the cis-five-membered ring product 35 was concluded by comparison of the 13C NMR data of the cis- and trans-isomers of 35.

An analogous mechanism in the case of the methallyl substituent 25 (entry 2) accounts for the formation of the mixture of the five- and six-membered rings 36 and 37, respectively. The formation of the five-membered rings 36 was proven by reduction of the mixture with tri-n-butyltin hydride to give 57 (Chart 1). The relative configuration of trans-36 was secured by NOE difference 1H NMR techniques. Irradiation of the methylene group adjacent to the chlorine atom showed an enhancement of H3, whereas irradiation of the methyl function did not. The more stable tertiary carbocation 50 (R = Me, eq 3) is less prone to be stabilized by the nitrogen atom and thus leads to a considerable amount of the six-membered rings 37. The stereochemistry of the cis- and trans-products was assigned by subjecting trans-37 to NOE difference 1H NMR techniques; irradiation of the methyl function showed an enhancement of the signal of one of the H6 protons and of the broad signal of both H4 protons. The fact that the signal of only one of the H6 protons was enhanced leads to the conclusion that the methyl group is in the axial position. In view of the proposed conformation of the intermediate hydrazonium species, the ester function is expected to be axially oriented. When formic acid was used for the cyclization (entry 3), only the trans six-membered ring 38 was found. The tertiary carbocation 50 (R = Me) probably gives a faster reaction with formate as a result of the large excess of the nucleophile so that ring contraction is less likely to occur.

Cyclization of the prenyl precursor 26 (entries 4 and 5) afforded the expected five-membered rings 39 and 40 with a trans-relationship between both substituents. Surprisingly, the crotol precursor 27 (entry 6) also gave only a mixture of the trans-five-membered ring products 41.
The *trans*-relationship between the substituents of the products 39, 40 and 41 is in accordance with the expected chair-like conformation 55 leading to the most favorable transition state (eq 5). The preference for the formation of a five-membered ring in the case of the crotyl precursor 27 is remarkable, because in similar cationic cyclizations six-membered rings are generally obtained. For example, comparable *N*-acyliminium ion precursors led to exclusive formation of six-membered rings.\(^{18b}\) Reduction of the cyclization product 41 with tri-*n*-butyl tin hydride afforded 58, thus confirming the formation of the five-membered ring. The *trans*-orientation was deduced from NOE difference \(^{1}H\) NMR techniques. Irradiation of the methyl substituent of 41 showed an enhancement of the signal of H3.

Additional evidence for the preference for the formation of five-membered rings was obtained upon cyclization of the allene precursor 28 (entry 7). Treatment of 28 with titanium tetrachloride afforded the five-membered rings 42 as a mixture of (E)/(Z)-isomers that could not be separated by flash chromatography. A mechanism that accounts for the formation of 42 is shown in eq 6. Initially, cyclization takes place to afford the vinylic cation 59. This intermediate rearranges via a 1,2-H shift to the more stable tertiary allylic cation 60, which is trapped by chloride to afford 42.

The seven-membered rings 43 were obtained upon cyclization of the butenyl precursor 29 (entry 8). Cyclization of the dibenzyl precursor 30 took place smoothly to give 44 in excellent yield (entry 9) although cyclization involving the benzyl function was not observed in any of the other reactions in table I. This is remarkable and might be partly explained by the difference in nucleophilicity with the other substituents, but also by the strong preference for the formation of five-membered rings. Presumably, other systems are likely to adopt a conformation in which the relatively large benzyl function is moved away from the glyoxylate moiety and thus will be less available for cyclization.

Another way to inhibit the ring contraction was observed upon cyclization of the allylsilane 31 (entry 10). Treatment with diethylaluminum chloride initially led to the silicon stabilized carbocation 61 (eq 7) which gave a fast elimination to the exocyclic double bond. An indication that formation of six-membered rings in such systems is a relatively slow process, is seen in entry 11. Treatment of the allylsilane precursor 31 with trifluoroacetic acid afforded 46 as a single product, which is explained by protodesilylation of 31 to the methallyl precursor 25 (not isolated), followed by cyclization to the expected six-membered ring 46 (treatment of 31 with formic acid gave the corresponding formate 38 in 58% yield).
The fact that the cyclization product 45 appeared to be stable in formic acid indicates that the formation of 46 is not simply a result of addition of formic acid to the double bond after cyclization.

In an analogous way, the propargylsilane 32 (entry 12) was treated with boron trifluoride etherate to give the allene 47 in a rather poor yield.

A striking difference was observed between cyclization of the (£)~ and (Z)-vinylsilanes 33 and 34 (entries 13 and 14). The chair-like transition state conformations of both starting materials are visualized in eqs 8 and 9, respectively. The (£)-vinylsilane 33 will react via a chair-like conformation to the cyclic cationic intermediate 62 in which the trimethylsilyl group occupies the equatorial position. Because the β-C-Si bond is not coplanar with the vacant p-orbital, stabilization of the positive charge by the silicon atom and subsequent elimination is not likely to take place, thus leading to a ring contraction via the aziridinium intermediate 63. Attack of chloride affords the final product 48. The stereochemistry of the product was confirmed by subjecting 48 to NOE difference 1H NMR techniques, showing an enhancement of only H3 upon irradiation of the proton adjacent to the silicon atom.

Cyclization of the (Z)-precursor 34 will occur via conformation 64 in which the trimethylsilyl group is axially oriented. In this orientation, maximal α-π hyperconjugative stabilization of the developing positive charge is possible, followed by fast elimination to the unsaturated six-membered ring 49, thereby excluding the formation of the aziridinium intermediate. Considering these mechanistic details, starting from the precursor 34, that was obtained as a 1:1.2 mixture of (£)- and (Z)-isomers, the corrected yields for 48 and 49 (entry 14) are 70% and 90%, respectively. Comparing the yield of the five-membered ring product 48, with the yield of 48 from the pure (£)-precursor 33 (entry 13), it is evident that the (Z)-isomer leads to exclusive formation of the six-membered ring 49.

These observations are in full accord with results published by Overman and co-workers,31 who reported the (Z)-vinylsilane to be at least 7000 times more reactive than its (£)-analog in iminium ion cyclizations.

DEPROTECTION REACTIONS

The sequence of deprotection reactions developed for compound 35 is shown in eq 10. First, the Alloc group was converted into the acid-labile Boc group (eq 10) in a one-pot procedure via a so-called transprotection reaction {Pd(PPh3)4 (cat), Bu3SnH (1,1 equiv), BnCO2 (2 equiv), CH2Cl2, rt}.20
Hydrogenation of 65 (10% Pd/C, HCl (cat)) led to smooth removal of the benzyl group to give 66, which was readily hydrolyzed to the HCl-salt 67 of the free α-hydrazino acid.

The structure of the five-membered ring 66, including the trans-relationship between the substituents was secured by an X-ray crystallographic analysis of 66 as depicted in Fig I. Beside the trans-relationship, it clearly shows the difference between the almost planar carbamate nitrogen atom (N2) and the pyramidal amine nitrogen atom (N1).

Cyclic α-hydrazino acid derivatives

The desired transprotected products could not be obtained in all cases. Transprotection of the five-membered rings proceeded in reasonable yields (entries 1 and 5), whereas the six-membered rings 44 and 45 also gave deprotection of the Alloc group to give the corresponding oxidized products 71 and 72 (entries 3 and 4). Apparently, the reaction with di-tert-butyl dicarbonate is very sensitive to steric hindrance caused by the benzyl substituent and the methyl ester, which is more pronounced in the six-membered rings. The formation of the oxidized products might be explained by decarboxylation of the initially formed tin carbonate 76,23 which will give a ring inversion to the thermodynamically more stable hydrazine 77 (eq 11).33 Once the ring inversion has taken place, oxidation occurs to give 72. Attempts to introduce smaller electrophiles like an acetyl function also failed.

(eq 11)

The seven-membered ring 42 (entry 3), however, afforded the transprotected product 69 in a reasonable yield. Probably, the methyl ester causes less steric strain in a larger, more flexible ring.

Analogous to the hydrazino acid derivative 65, debenzylation of 69 and 73 provided a good yield of the corresponding hydrazines 74 and 75 (entries 2 and 5).

CONCLUSIONS

It is evident that a large variety of cyclic α-hydrazino acid derivatives can be efficiently synthesized via this method. Several conclusions can be drawn from the outcome of the cyclization reactions. The cyclizations show a strong preference for the formation of five-membered rings, particularly illustrated by the crotyl and allene precursor, which both produced the corresponding five- instead of six-membered rings. Furthermore, if a six-membered ring is formed during the cyclization, stabilization of the cationic intermediate by the amine nitrogen atom may take place, leading to a five-membered ring via an aziridinium intermediate. This ring contraction can be inhibited by stabilization of the developing positive charge by a β-silicon substituent, followed by a fast elimination process. A remarkable difference in reactivity is observed between the benzyl group and the non-aromatic π-nucleophiles; cyclization of the benzyl group only takes place if no other nucleophile is present in the molecule. Deprotection is carried out by the transprotection method. This method fails in most six-membered ring cases, probably due to steric hindrance.

EXPERIMENTAL

All reactions were carried out under an inert atmosphere of dry nitrogen, unless otherwise described. Standard syringe techniques were applied for transfer of Lewis acids and dry solvents. Infrared (IR) spectra were obtained from CHCl₃ solutions, unless indicated otherwise, using a Perkin-Elmer 1310 spectrophotometer and wavelengths (v) are reported in cm⁻¹. Proton nuclear magnetic resonance (¹H NMR) spectra were determined in CDCl₃ (unless indicated otherwise) using a Bruker AC 200 (200 MHz), a Bruker WM 250 (250 MHz) or a Bruker AMX 300 (300 MHz) spectrometer. The latter three machines were also used for ¹³C NMR (APT) spectra (50, 63 and 75 MHz respectively) in CDCl₃ (unless indicated otherwise). Chemical shifts (δ) are
given in ppm downfield from tetramethylsilane. Low and high resolution mass spectra were recorded by using a Varian MAT 711 or a VG Micromass ZAB-2HF instrument. Elemental analyses were performed by Domnis u. Kolbe Mikroanalytisches Laboratorium, Mülheim a.d. Ruhr, Germany. \( R_f \) values were obtained by using thin-layer chromatography (TLC) on silica gel-coated plastic sheets (Merck silica gel 60 F254) or Janssen Chimica silica gel (Q.030-0.075 mm). Melting and boiling points are uncorrected. CH2Cl2 was distilled from P2O5 and stored over MS 4Å under an atmosphere of dry nitrogen. TiCl4 and SnCl4 were distilled and stored under a dry nitrogen atmosphere as a solution in CH2Cl2. BF3-OEt2 was distilled and stored under a dry nitrogen atmosphere. Dry THF and Et2O were distilled from sodium benzophenone ketyl prior to use.

α-Acetoxy-1-(allyloxycarbonyl)-2-benzyl-2-((E)-3-(trimethylsilyl)-2-propenyl)hydrazineacetic acid methyl ester (33). Following the general procedure B, a solution of 22 (5.93 g, 18.6 mmol) in toluene (200 mL) was reacted with methyl glyoxylate (13.1 g, 150 mmol) for 42 h and acetylated with Ac₂O (5.8 mL, 61 mmol) in pyridine (60 mL). Concentration in vacuo and fc (ethyl acetate/hexane 1:4) afforded 34 (2.17 g, 4.84 mmol, 79%) as a light yellow oil, (E)/(Z) 1:1.2, IR v 1740, 1680, 1375, 690; 1H NMR (200 MHz) δ -0.06, 0.00 (s, 9 H, (CH₃)₂Si), 1.43, 1.63 (s, 2 H, CH₂Si), 1.91 (s, 3 H, C(O)CH₂), 3.25-3.70 (m, 2 H, NCH₂), 3.66 (s, 3 H, CO₂CH₃), 3.80 (d, J = 12.6 Hz, 1 H, C≡CHPh), 3.81 (s, 3 H, CO₂CH₃), 4.50-4.75 (m, 3 H, OCH₂ and C=CH₂), 5.15-5.50 (m, 2 H, CH=CH₂), 5.68-5.77 (m, 2 H, CH=CH₂), 5.80-6.15 (m, 1 H, CH₂=CH₂), 6.50, 6.60 (s, 1 H, NCH), 7.24-7.32 (m, 5 H, ArH).

α-Acetoxy-1-(allyloxycarbonyl)-2-benzyl-2-((Z)-3-(trimethylsilyl)-2-propenyl)hydrazineacetic acid methyl ester (34). Following the general procedure B, a solution of 23 (1.95 g, 6.13 mmol) in toluene (60 mL) was reacted with methyl glyoxylate (2.70 g, 30.7 mmol) for 42 h and acetylated with Ac₂O (17.6 mL, 0.19 mol) in pyridine (200 mL). Concentration in vacuo and fc (ethyl acetate/hexane 1:4) afforded 35 (some signals appear as rotamers) 2.46-2.72 (m, 2 H, CH₂Ph), 4.88 (s, 1 H, C≡CHH), 5.15-5.50 (m, 2 H, CH=CH₂), 5.75-6.10 (m, 1 H, =CH), 6.42 (s, 1 H, NCH), 7.22-7.34 (m, 5 H, ArH).

General procedure C for the cyclization reactions with Lewis acids. To a 0.1 M solution of the hydrazide in CH₂Cl₂ was added TiCl₄, SnCl₂ (2 equiv of a solution in CH₂Cl₂) or Et₂AlCl (2 equiv of a 1.0 M solution in toluene) at -78 °C by a syringe. The mixture was stirred at -78 °C for 15 min and for 5-18 h at rt. The reaction mixture was poured into cold aq. NaHCO₃ and the resulting suspension was filtered over Celite and extracted with CH₂Cl₂ (3 ×). The combined organic layers were dried (MgSO₄), filtered and concentrated in vacuo. Purification of the residue by fc afforded the pure cyclization product(s).

rel-(3S,5S)-2-(Allyloxycarbonyl)-1-benzyl-5-(chloromethyl)-3-pyrazolidinecarboxylic acid methyl ester (trans-35). According to the general procedure C, a solution of 24 (500 mg, 1.33 mmol) in CH₂Cl₂ (13 mL) was cyclized by using SnCl₂ (1.33 mL of a 2.0 M solution, 2.66 mmol). Work-up and fc (ethyl acetate/hexane 1:4) afforded 35 (352 mg, 1.00 mmol, 75%) as a colorless oil, cfr 1:5, Rf 0.25. trans-35: IR v 1740, 1680, 1375, 690; 1H NMR δ 2.46-2.72 (m, 2 H, CH₂Ph), 3.11 (dd, J = 8.8, 10.6 Hz, 1 H, CH/HCl), 3.31-3.44 (m, 2 H, CH/HCl and H5), 3.80 (d, J = 12.6 Hz, 1 H, CH/HPh), 3.81 (d, 3 H, CO₂CH₃), 5.36-5.50 (m, 2 H, CH=CH₂), 5.75-6.10 (m, 1 H, =CH), 6.42 (s, 1 H, NCH), 7.22-7.34 (m, 5 H, ArH).
Cyclic α-hydrazino acid derivatives

Cyclization of 25 with Et₂AlCl. Following the general procedure C, a solution of 25 (982 mg, 2.52 mmol) in CH₂Cl₂ (25 mL) was treated with Et₂AlCl (7.55 mL of a 1.0 M solution in toluene, 7.55 mmol). IR ν 1745, 1700, 1680, 690; 1H NMR (200 MHz) δ 1.39 (s, 9 H, (CH3)2C), 1.56 (d, J = 6.7 Hz, 3 H, CH3), 3.03-3.10 (m, 3 H, H4 and 2 × H5), 3.69-3.85 (m, 2 H, CH2Ph), 3.82 (s, 3 H, CO2CH3), 4.15-4.30 (m, 2 H, H3 and CH2Cl), 7.26-7.46 (m, 3 H, ArH); 13C NMR (50 MHz) δ 24.1 (CH3), 28.2 (CH2Ph), 51.5 (C4), 52.6 (CO2CH3), 54.5 (C5), 57.5 (CHC1), 61.8 (CH2Ph), 63.2 (C3), 81.0 (CH3), 127.4, 128.3, 129.6 (ArH), 137.5 (ArC), 172.9 (C(O)); MS (EI, 70 eV) m/z (relative intensity) 382 (M+, 4), 281 (58), 245 (15), 231 (9), 91 (100); HRMS calcd for C15H22N2O4Cl 382.1659, found 382.1635.
Deprotection of 44. Following the general procedure D, a solution of 44 (200 mg, 0.55 mmol) in CH₂Cl₂
(3 mL) was treated with Boc₂O (139 µL, 0.61 mmol), Pd[PPh₃]₄ (13 mg, 0.011 mmol) and n-Bu₃SnH (160 µL, 0.61 mmol). Concentration in vacuo and flash chromatography (ethyl acetate/hexane 1:4) afforded 3-
benzyl-2-((tert-butoxycarbonyl)-1,2,3,4-tetrahydro-1-phthalazinecarboxylic acid methyl ester
(70) (118 mg, 0.31 mmol, 56%) as a colorless oil, Rf 0.35 and 3-benzyl-3,4-dihydro-1-
phthalazinecarboxylic acid methyl ester (71) (35 mg, 0.12 mmol, 22%) as a colorless oil, Rf 0.32. 70:
IR v 1735, 1670, 1130, 690; ¹H NMR (200 MHz) δ (some signals appear as rotamers) 1.52, 1.53 (s, 9 H, (CH₃)₃C), 3.30-4.50 (br m, 7 H, CO(CH₃)), 3.43 (s, 2 H, 2 x H₄), 3.75 (s, 3 H, CO₂CH₃), 4.69 (s, 2 H, CH₂Ph), 6.89-6.94 (m, 1 H, ArH), 7.23-7.40 (m, 7 H, ArH), 8.08-8.13 (m, 1 H, ArH).

1-Benzyl-3-methylene-1,4,5,6-tetrahydro-1-phthalazinecarboxylic acid methyl ester (72). Following the general procedure D, a solution of 44 (100 mg, 0.30 mmol) in CH₂Cl₂ (3 mL) was treated with Boc₂O (153 µL, 0.67 mmol), Pd[PPh₃]₄ (11 mg, 9.1 x 10⁻³ mmol) and n-Bu₃SnH (88 µL, 0.33 mmol). Concentration in vacuo and flash chromatography (ethyl acetate/hexane 1:4) afforded 72 (58 mg, 0.24 mmol, 78%) as a colorless oil, Rf 0.25. ¹H NMR (200 MHz) δ 3.14 (s, 2 H, 2 x H₄), 3.43 (s, 2 H, 2 x H₄), 3.84 (s, 3 H, CO₂CH₃), 4.61 (s, 2 H, CH₂Ph), 4.93 (s, 1 H, C=CHH), 5.03 (s, 1 H, C=CH₂H), 7.24-7.35 (m, 5 H, ArH).

rel-(3R,4S,5S)-1-Benzyl-2-((tert-butoxycarbonyl)-5-(chloromethyl)-4-((trimethylsilyl)-3-
pyrazolidinecarboxylic acid methyl ester (73). Following the general procedure D, a solution of 48
(434 mg, 1.02 mmol) in CH₂Cl₂ (15 mL) was treated with Boc₂O (0.52 mL, 2.25 mmol), Pd[PPh₃]₄ (35 mg, 0.031 mmol) and n-Bu₃SnH (0.30 mL, 1.13 mmol). Concentration in vacuo and fe (ethyl acetate/hexane 1:4) afforded 73 (288 mg, 0.65 mmol, 64%) as a light yellow oil, Rf 0.60. IR v 1760, 1690, 1250, 840, 690; ¹H NMR (200 MHz) δ 0.11 (s, 9 H, (CH₃)₃C), 1.45 (s, 9 H, (CH₃)₂C), 1.97 (t, J = 9.0 Hz, 1 H, H₄), 3.06 (dd, J = 11.4, 4.3 Hz, 1 H, CH(/CH₃)), 3.24 (dd, J = 11.4, 3.4 Hz, 1 H, CH(CH₃)), 3.43-3.50 (m, 1 H, H₅), 3.77 (s, 3 H, CO₂CH₃), 3.96 (d, J = 12.7 Hz, 1 H, CH/Ph), 4.32 (d, J = 12.7 Hz, 1 H, CH/Ph), 4.99 (d, J = 9.0 Hz, 1 H, H₃), 7.26-7.51 (m, 5 H, ArH); ¹³C NMR (50 MHz) δ 1.79 (CH₂S), 28.3 (CH₃C), 35.1 (C4), 47.9 (CH₂C), 52.0 (CO₂CH₄), 62.0 (C5), 63.2 (CH₂Ph), 68.7 (C₅), 80.8 (CH₂C), 127.4, 128.2, 129.4 (ArH), 138.1 (ArC), 155.7, 172.8 (C(O)); MS (El, 70 eV) m/z (relative intensity) 440 (M⁺, 26), 340 (90), 325 (12), 185 (13), 139 (5), 133 (8), 91 (100); HRMS calculated for C₂₃H₇₇N₂O₄Si 440.1898, found 440.1905.

2-(tert-Butoxycarbonyl)-5-chloroexahydro-1H-diazepine-3-carboxylic acid methyl ester
(74). A mixture of 69 (60 mg, 0.10 mmol), Pd/C (11 mg of 10% Pd on C, 0.01 mmol) and one drop of a 3 M
HCl/MeOH solution in MeOH (5 mL) was stirred under a H₂-atmosphere for 1 h. After filtration over Celite, the solution was concentrated in vacuo, taken up in aq satd NaHCO₃ (10 mL) and extracted with CH₂Cl₂ (3 x 10 mL). The combined organic layers were dried (MgSO₄), filtered, concentrated in vacuo and chromatographed (ethyl acetate/hexane 1:2) to afford 74 (20 mg, 0.065 mmol, 65%) as a colorless oil, Rf 0.25. 21. Reaction with larger amounts of allyl chloroformate led to substantial amounts of 1,2-hydrazinedicarboxylic acid diallylester.

28. The corresponding alcohol 3-(trimethylsilyl)-1-propanol was obtained as a mixture of (E)/(Z)-isomers upon catalytic hydrogenation of 3-(trimethylsilyl)-1-propynol (ref. 26), although this reaction has been reported to proceed stereospecifically.

33. This inversion is also observed after cleavage of the carbamate group of pipecolic acid derivatives and is caused by the relief of pseudo-allylic 1,3-strain. (see also refs. 18 and 19).
