Cerebral Folate Deficiency Syndrome

TO THE EDITOR: Ramaekers et al. (May 12 issue) report 28 patients with the cerebral folate deficiency syndrome characterized by decreased levels of 5-methyltetrahydrofolate (5MTHF) in the cerebrospinal fluid caused by autoantibodies’ blocking of folate transport into the brain. The patients benefited from folinic acid supplementation.

The clinical features of this syndrome fit with other neurodegenerative disorders. According to previous papers by the authors, the latter disorders can be associated with cerebral folate deficiency as a secondary phenomenon.1,2,4 Patients with secondary cerebral folate deficiency (e.g., the Rett syndrome) potentially benefit from folinic acid supplementation.2,4 The authors do not report the presence or absence of folate-receptor autoantibodies in secondary cerebral folate deficiency. Before claiming that the cerebral folate deficiency syndrome is a separate entity, the investigators should demonstrate that it is a unique, autoantibody-mediated disease, different from secondary cerebral folate deficiency.

THE AUTHORS REPLY: Within the group of neuropsychiatric conditions associated with cerebral folate deficiency, infantile-onset cerebral folate deficiency syndrome can be delineated as a separate and recognizable clinical entity, which can begin manifesting itself at the age of four months, when the only identifiable abnormality is a low level of 5MTHF in the cerebrospinal fluid.1,2 This means that other conditions that involve secondary cerebral folate deficiency must be excluded before a firm diagnosis of infantile cerebral folate deficiency syndrome is established.3

The identification of blocking folate-receptor autoantibodies in the serum of most patients with infantile-onset cerebral folate deficiency syndrome merely reflects a specific autoimmune mechanism that explains the blocked folate transfer to the brain. Among the few patients without these folate-receptor autoantibodies, alternative causes may be responsible for the low levels of 5MTHF in cerebrospinal fluid.

Since blocking folate-receptor autoantibodies impair folate transport across the placenta and blood–cerebrospinal fluid barriers,3 we cannot exclude the possibility that they also play a role in the pathogenesis of secondary cerebral folate deficiency.4,5

Response of a Nonmalignant Pleural Effusion to Bevacizumab

TO THE EDITOR: The potential role of vascular endothelial growth factor in malignant as well as non-malignant pleural effusion1,2 prompted us to use bevacizumab, a monoclonal antibody against vascular endothelial growth factor, in a 68-year-old man with primary cardiac amyloidosis who had severe dyspnea and underwent repeated thoracenteses for pleural effusions. Cytologic assessments of the
