Abstract of the lecture

NON - ARCHIMEDEAN DIFFERENTIATION

held on Tuesday, June 5, 1979 at the "VI Jornadas de Matemáticas Hispano-Lusas" organized by the University of SANTANDER,

by

W.H. Schikhof

§ 1. Introduction.

The subject is part of the so-called non-archimedean (or ultrametric) analysis. Roughly speaking, one may say that this is the analysis that one obtains when replacing in the "classical" analysis IR or C by a non-archimedean valued field K.

A non-archimedean valued field is a (commutative) field K, together with a map \(| \cdot | : K \to IR\) (the valuation) satisfying

\[ |a| \geq 0 , \quad |a| = 0 \text{ iff } a = 0 \]
\[ |ab| = |a| |b| \]
\[ |a+b| \leq \max(|a|,|b|) \] (the strong triangle inequality)

for all \(a, b \in K\).

We have the following remarks.

(1) Apart from IR or C, every complete valued field is non-archimedean.

(2) If \(K\) is a non-archimedean valued field and if \(L \supset K\) is an overfield of \(K\) then the valuation on \(K\) can be extended to a non-archimedean valuation on \(L\).

(3) If \(K\) is a (non-archimedean) valued field then its completion \(\hat{K}\) (with respect to the metric \((x,y) \mapsto |x-y|\) can, in a natural
way, be given the structure of a non-archimedean valued field.

In the sequel we exclude the so-called trivial valuation given by

\[ |x|' = \begin{cases} 0 & \text{if } x = 0 \\ 1 & \text{if } x \neq 0. \end{cases} \]

The non-archimedean analysis has several branches, similar to the classical analysis. Thus we have non-archimedean functional analysis, harmonic analysis, theory of analytic functions in one or several variables, etc.

In this talk we consider a more elementary subject, namely infinitesimal calculus in \( K \). More specifically, we want to see what remains of the so-called Fundamental Theorem of Calculus (in \( \mathbb{R} \)) that states that the operations of differentiation and integration are in some sense each others inverses.

§ 2. Differentiation in \( K \). Let \( X \subset K \) be a subset without isolated points. A function \( f : X \to K \) is called differentiable if for all \( a \in X \)

\[ f'(a) := \lim_{x \to a} \frac{f(x) - f(a)}{x - a} \]

exists. The proof of the well known rules (sum-, product-, chain-rule) can formally be taken over from the classical theory. Thus, a rational function is differentiable if it has no poles on \( X \). An analytic function \( x + \sum_{n} a_{n} x^{n} \) is differentiable on \( \{ x : |x| < (\lim \sqrt[n]{a_{n}})^{-1} \} \).

Deviations from the classical theory appear when we look at the functions whose derivative vanishes everywhere. For example,
let \( \epsilon > 0, a \in K \). Then \( B(a, \epsilon) := \{ x \in K : |x-a| < \epsilon \} \) is an open-
and-closed subset of \( K \), hence \( \xi_B(a, \epsilon) \), defined by

\[
\xi_B(a, \epsilon)(x) := \begin{cases} 
1 & \text{if } x \in B(a, \epsilon) \\
0 & \text{elsewhere}
\end{cases}
\]

is differentiable and \( \xi'_B(a, \epsilon) = 0 \).

Locally constant functions all have derivative zero. On the other
hand they form a uniformly dense subset of \( C(X) \), the space of all
continuous functions: \( X \rightarrow K \).

Even worse: let \( \mathbb{Q}_p \) the field of the \( p \)-adic numbers and let
\( \mathbb{Z}_p := \{ x \in \mathbb{Q}_p : |x| \leq 1 \} \). Then the function \( f : \mathbb{Z}_p \rightarrow \mathbb{Q}_p \) defined by

\[
f(\sum_{n=0}^{\infty} a_n p^n) = \sum_{n=0}^{\infty} a_n p^{2n} \quad (\sum_{n=0}^{\infty} a_n p^n \in \mathbb{Z}_p)
\]

satisfies \( |f(x)-f(y)| = |x-y|^2 \) for all \( x, y \in \mathbb{Z}_p \). So \( f' = 0 \) but \( f \)
is injective, hence not locally constant.

The above example shows also that a Mean Value Theorem is necessa-
ri ly absent in our theory.

Notice that the difficulties encountered above also appear when we
study differentiability of functions \( f : \mathbb{D} \rightarrow \mathbb{R} \), where \( \mathbb{D} \subset [0,1] \)
is the Cantor set. So it is the domain of \( f \) that is responsible
for the troubles rather than its range.

§ 3. Continuously differentiable functions.

If we follow naively the path of the classical analysis and define

\[
C^1(X) := \{ f : X \rightarrow K, f \text{ is differentiable, } f' \text{ is continuous} \}
\]

then we run up against difficulties.

First of all, one can prove that \( C^1(\mathbb{Z}_p) \) (with the norm
f \mapsto \max(||f||_{\infty}, ||f'||_{\infty}) is not a Banach space. In fact one shows that for every pair of continuous functions \( f, g : Z \rightarrow \mathbb{Q} \), there exists a sequence \( f_1, f_2, \ldots \) in \( C^1(Z) \) for which both \( f_n \rightarrow f \) and \( f'_n \rightarrow g \) uniformly.

What is worse, we have no local invertibility theorem for such \( C^1 \) functions.

In fact, let \( f : Z \rightarrow \mathbb{Q} \) be defined by

\[
f(x) = \begin{cases} 
    -p^{2n} & \text{if } |x-p^n| < p^{-2n} \\
    x & \text{elsewhere}
\end{cases} \quad (n \in \mathbb{N})
\]

Then \( f'(x) = 1 \) for all \( x \in Z \). But \( f(p^n) = f(p^n - p^{2n}) \) for all \( n \in \mathbb{N} \), so \( f \) is not even locally injective at 0.

Therefore we are led to define:

Let \( f : X \rightarrow K \). Put

\[
\phi f(x,y) := \frac{f(x) - f(y)}{x-y} \quad (x,y \in X, x \neq y).
\]

We say that \( f \in C^1(X) \) if \( \phi f \) can continuously be extended to a function \( \bar{\phi}f : X \times X \rightarrow K \).

Then \( BC^1(X) := \{ f \in C^1(X) : f \text{ and } \phi f \text{ are bounded} \} \) is a Banach space under \( f \mapsto ||f||_1 := \max(||f||_{\infty}, ||\phi f||_{\infty}) \).

Further, if \( f \in C^1(X) \), \( f'(a) \neq 0 \) for some \( a \in X \), then \( f \) has a \( C^1 \)-inverse, locally at \( a \).

**Theorem.** Differentiation is a continuous surjection \( BC^1(X) \rightarrow BC(X) \).

(here \( BC(X) \) is the space of all bounded continuous functions with the supremum norm)

§ 4. "Integration".

Next, we want to define an "indefinite integral" \( P : BC(X) \rightarrow BC^1(X) \)
(an analogue of \((Pf)(x) := \int_0^X f(t)dt\) for real functions) such that \(DP\) is the identity on \(BC(X)\).

A natural try is first to find an analogue of the Lebesgue measure in \(K\). But this turns out to be a dead end road. For example if \(K = \mathbb{Q}_p\) there does not exist a nonzero translation invariant bounded additive \(\mathbb{Q}_p\)-valued function \(m\) defined on the compact open subsets of \(\mathbb{Z}_p\). (By translation invariance \(|m(p^n\mathbb{Z}_p)| = p^n|m(\mathbb{Z}_p)| \to \infty\) if \(m(\mathbb{Z}_p) \neq 0\). For similar reasons it goes wrong for every local field \(K\).

Following the ideas of Dieudonné, Treiber, we define for \(f \in BC(X)\)

\[
(Pf)(x) := \sum_{n=1}^{\infty} f(x_n)(x_{n+1} - x_n) \quad (x \in X)
\]

Here the \(x_n\) are defined as follows. For each \(n \in \mathbb{N}\) the equivalence relation \(\approx_n\) defined by \(x \approx_n y\) if \(|x-y| < \frac{1}{n}\) yields a partition of \(X\) into balls. Choose a center in each ball and let \(R_n\) be the set of these centers.

For each \(x \in X\) and \(n \in \mathbb{N}\), \(x_n\) is defined by \(x_n \in R_n\), \(|x_n - x| < \frac{1}{n}\).

**Theorem.** (A NON-ARCHIMEDEAN FORM OF THE FUNDAMENTAL THEOREM).

\(P\) is a linear isometry of \(BC(X)\) into \(BC^1(X)\). \(DP\) is the identity on \(BC(X)\), whereas \(PD\) is a projection of \(BC^1(X)\) onto a complement of \(\{f \in BC^1(X) : f' = 0\}\).

§ 5. Generalizations of the Fundamental Theorem.

We may ask whether there exists some form of the Fundamental Theorem for functions belonging to spaces, larger than \(BC(X)\), \(BC^1(X)\)
respectively. (For example, compare the classical theorem on $L^1$-functions versus absolutely continuous functions).

We have the following striking fact that has no counterpart in classical analysis. We say that $g : X \to K$ is of the first class of Baire if there exists a sequence $g_1, g_2, \ldots$ of continuous functions $X \to K$ such that $\lim g_n = g$ pointwise.

**THEOREM.** (a) Let $f : X \to K$ be differentiable. Then $f'$ is of the first class of Baire.

(b) Let $g : X \to K$ be of the first class of Baire. Then $g$ has an antiderivative.

Let $B^1(X)$ be the Banach space consisting of all bounded functions $X \to K$ of the first class of Baire with respect to the supremum norm.

Let $BD(X)$ be the Banach space of all differentiable $f : X \to K$ for which both $f$ and $\Phi f$ are bounded, with respect to the norm $f + \|f\|_\infty \vee \|\Phi f\|_\infty$. Then we have

**THEOREM.** Differentiation is a quotient map $BD(X) \xrightarrow{D} B^1(X)$.

If $K$ has discrete valuation then there exists a continuous linear $P : B^1(X) \to BD(X)$ for which $DP$ is the identity on $B^1(X)$.

**Notes.**

1. The construction of the above $P$ is awful and, contrary to § 4, $P$ does not resemble an indefinite integral in any way.

2. If the valuation of $K$ is dense the existence of such a $P$ is still an open question.
§ 6. Restriction of the Fundamental Theorem.

In classical analysis, we have that if $f \in C^n$ then
\[ x \mapsto \int_0^x f(t) \, dt \text{ is in } C^{n+1}. \]
In our situation we define for $f : X \rightarrow K$:

$f \in C^2(X)$ if the function $\phi_2 f$, defined by

\[ \phi_2 f(x,y,z) = \frac{\phi_1 f(x,z) - \phi_1 f(y,z)}{x-y} \quad (x,y,z \in X, x \neq y, y \neq z, x \neq z) \]

can continuously be extended to $\phi_2 f : X^3 \rightarrow K$. Similarly, we define $C^3(X), C^4(X), \ldots$. Let $C^\infty(X) := \bigcap_{n=1}^{\infty} C^n(X)$.

The map $P$, defined in § 4, does not always map $C^1$-functions into $C^2$-functions. But we have (notations as in § 4)

**THEOREM.** Let the characteristic of $K$ be unequal to 2. Then the map

$P_2$ defined via

\[ (P_2 f)(x) := \sum_{n=1}^\infty (x \cdot \frac{1}{n+1} - x) + \frac{1}{2} \sum_{n=1}^\infty (x \cdot \frac{1}{n+1} - x)^2 \quad (x \in X) \]

maps $C^1(X)$ into $C^2(X)$ and $(P_2 f)' = f$ for all $f \in C^1(X)$.

Similarly, one can define antiderivation maps $P_n : C^{n-1}(X) \rightarrow C^n(X)$ (in case the characteristic of $K$ is unequal to 2, 3, ..., $n$).

**OPEN QUESTION.** Let $K$ have characteristic 0. Does every $f \in C^\infty(X)$ have a $C^\infty$-antiderivative?
