Electromagnetic wave propagation in a one-dimensional magnetic photonic crystal (MPC) made of bigyrotropic magnetic yttrium–iron garnet and nonmagnetic gadolinium–gallium garnet is theoretically investigated. Band gaps in the electromagnetic spectrum are numerically obtained and appear to depend on the helicity and direction of light propagation through the MPC. © 2004 American Institute of Physics. [DOI: 10.1063/1.1825060]

During the last 15 years, photonic band gap (PBG) materials, or photonic crystals (PCs), have been the objects of intense theoretical and experimental investigation because of promising applications in optoelectronics and telecommunication. The PCs are artificially fabricated structures with one-, two-, or three-dimensional periodic order, with structural periods that are comparable to the wavelength of the incident electromagnetic wave (EMW). The main attraction of PCs is the existence of forbidden regimes or band gaps in their transmittance spectra.

Quite recently magnetic materials have been incorporated into PCs, which has led to the recognition of new peculiarities of EMW propagation in PCs, e.g., nonreciprocity and unidirectionality, that can be tuned by the application of a magnetic field. In magnetic photonic crystals (MPCs), forbidden regimes can exist in both the optical and the microwave portions of the electromagnetic spectrum. The PBGs can be found by solving dispersion equations that take into account the periodicity of the permittivity tensor \( \epsilon_{ij} \) and the permeability tensor \( \mu_{ij} \).

Optical and magneto-optical effects (MO) in MPCs constructed from yttrium–iron garnet YIG \( \text{Y}_3\text{Fe}_5\text{O}_{12} \) have been theoretically investigated by several groups, including taking into account the magnetization-induced off-diagonal components of the permittivity tensor. Impurity-doped YIG crystals and films, which are transparent in the near-infrared (NIR) regime, are widely used in modern magneto-optics. For example, recently a miniature tunable broadband magneto-optical modulator based on a Bi-substituted YIG film was presented as the basis of new high-speed magneto-photonic devices. Also, enhanced Faraday rotation in an all-garnet MPC based on \( \text{Bi}_3\text{Fe}_5\text{O}_{12}/\text{Y}_3\text{Fe}_5\text{O}_{12} \) multilayers was reported. A remarkable property of YIG is its bigyrotropy, which is characterized by the fact that in the transparency regime its permittivity tensor and its permeability tensor have comparable contributions to the MO response. Ageev et al. measured the Faraday rotation at \( \lambda = 1150 \text{ nm} \) in impurity-doped YIG films with composition \( \text{Y}_3\text{Fe}_{3.88}\text{Sc}_{0.68}\text{Ga}_{0.44}\text{O}_{12} \), and showed that the off-diagonal components of both tensors have comparable effects. So, the correct description of wave propagation in YIG-containing structures requires that the solution of the Maxwell equations incorporate both the permittivity and the permeability tensors. In this letter, we investigate PBG effects in YIG-MPCs taking the bigyrotropy of YIG into complete account and find that the presence of band gaps strongly depends on the helicity and direction of the EMWs, leading to tunable, polarization selective magneto-photonic elements.

Let us consider a one-dimensional periodic structure composed of bigyrotropic (BG) YIG layers of thickness \( d_1 \) alternating with nonmagnetic GGG (\( \text{Gd}_3\text{Ga}_5\text{O}_{12} \)) layers of thickness \( d_2 \). This multilayer structure, or BG MPC, is supposed to be of infinite dimensions in the \( xy \) plane with the \( z \) axis normal to the layers. The unit cell with the period \( D = d_1 + d_2 \) contains a YIG layer and a GGG layer. The magnetization vector in the YIG layers is oriented along the \( z \) axis, as shown in Fig. 1, while we restrict ourselves to EMW propagation in the \( yz \) plane.

In the multilayer structure, components of the permittivity and the permeability tensors of the YIG layers are identified with the superscript \( (1) \), and those of the GGG layers with the superscript \( (2) \), respectively. Because YIG is bigyrotropic, its permittivity and permeability tensors, in general, are determined by Eqs. (2) and (3) of Ref. 5. Thus, the permittivity and permeability tensors of a BG cubic YIG layer magnetized along the \( z \) axis have the following nonzero components:

\[
\begin{align*}
\epsilon_{xx}^{(1)} &= \epsilon_{yy}^{(1)} = \epsilon_{zz}^{(1)} = \epsilon_0 + g_{12}^{(1,2)} m_z^2, \\
\epsilon_{cc}^{(1)} &= \epsilon_0 + g_{11}^{(1,2)} m_z^2, \\
\epsilon_{tr}^{(1)} = (\epsilon_{tr}^{(1)})^* &= i \epsilon_0 + i f^{(1)} m_z, \\
\mu_{xx}^{(1)} &= \mu_{yy}^{(1)} = \mu_{zz}^{(1)} = \mu_0 + g_{11}^{(1,2)} m_z^2, \\
\mu_{cc}^{(1)} &= \mu_0 + g_{11}^{(1,2)} m_z^2, \\
\mu_{xy}^{(1)} = (\mu_{xy}^{(1)})^* &= i \mu_0 + i f^{(1)} m_z.
\end{align*}
\]

Here and in the following, Gaussian units are implicit; \( m_z \) is the \( z \) component of the unit vector \( \mathbf{m} = M/M_z \), where \( M_z \) is...
the saturation magnetization; \( e^{(1,0)} \) and \( \mu^{(1,0)} \), respectively, are the nonzero components of the permittivity \( e^{(1,0)} \) and permeability \( \mu^{(1,0)} \) in the absence of magnetization or dc magnetic field; \( i = \sqrt{-1} \); while \( f^{(1,0)}(i\varepsilon) \), \( g^{(1,0)}(i\varepsilon) \) and \( h^{(1,0)} \) are nonzero components of the linear and the quadratic magneto-optical tensors; thus, \( e^{(1,0)} = e^{(1,0)}_x = e^{(1,0)}_y = e^{(1,0)}_z \), \( \mu^{(1,0)} = \mu^{(1,0)}_x = \mu^{(1,0)}_y = \mu^{(1,0)}_z \), \( f^{(1,0)}(i\varepsilon) = f^{(1,0)}(i\varepsilon) \), \( g^{(1,0)}(i\varepsilon) = g^{(1,0)}(i\varepsilon) \), \( h^{(1,0)} \) are diagonal, i.e.,

\[
\begin{align*}
\frac{\hat{\varepsilon}}{\hat{\varepsilon}_{zzz}} &= \varepsilon_{zzz}, \\
\frac{\hat{\mu}}{\hat{\mu}_{zzz}} &= \mu_{zzz}, \\
\frac{\hat{f}}{\hat{f}_{xyz}} &= f_{xyz}, \\
\frac{\hat{g}}{\hat{g}_{xyz}} &= g_{xyz}, \\
\frac{\hat{h}}{\hat{h}_{xyz}} &= h_{xyz}.
\end{align*}
\]

The permittivity and the permeability tensors of GGG are diagonal, i.e.,

\[
\begin{align*}
\varepsilon^{(2)}_{ij} &= \varepsilon^{(2,0)}_{ij} \delta_{ij}, \\
\mu^{(2)}_{ij} &= \delta_{ij},
\end{align*}
\]

where \( \delta_{ij} \) is the Kronecker delta.

As YIG is anisotropic, EMW propagation is best described using \( 4 \times 4 \) matrices. The transfer matrix (TM) method then yields the two dispersion equations\(^{15}\)

\[
\cos(q_1 L) = \frac{1}{4} [\text{Tr}(\hat{T}) \pm \sqrt{2 \text{Tr}(\hat{T}^2) - \text{Tr}(\hat{T}^2) + 8}],
\]

where \( q_1 \) and \( q_2 \) are the wave numbers of the EMW in the MPC; \( \hat{T} \) is the \( 4 \times 4 \) TM of the unit cell; and \( \text{Tr}(\cdot) \) indicates the trace. For the two-layer unit cell under consideration, we get

\[
\hat{T} = \hat{E}_2 \hat{S}_{(12)} \hat{E}_1 \hat{S}_{(12)},
\]

where the diagonal \( 4 \times 4 \) matrix

\[
\hat{E}_L = \text{diag}(\varepsilon^{(2,0)}_{zzz} d_z, -i\varepsilon^{(2,0)}_{zzz} d_z, -i\varepsilon^{(2,0)}_{zzz} d_z, -i\varepsilon^{(2,0)}_{zzz} d_z).
\]

The matrix \( \hat{E}_L \) describes a phase change inside the layer labeled \( L \) (\( L = 1, 2 \)),\(^{15}\) with \( \kappa^{(L)}_z \) as the \( z \) components of the wave vectors inside that layer. The quantities \( k^{(L)}_z \) depend on the mutual orientation of the wave vector and the magnetization direction inside the particular layer, as well as on the permittivity and permeability tensor components. In the YIG layer of the unit cell, \( k^{(1)}_z \) is

\[
\begin{align*}
(k^{(1)}_z)^2 &= \frac{1}{2} \left[ \frac{\varepsilon^{(1)}_1}{\varepsilon^{(1)}_1} + \frac{\mu^{(1)}_1}{\mu^{(1)}_1} \right] k^2 \\
&\quad - \Omega^2 [\mu^{(1)}_1 (\varepsilon^{(1)}_1 + \mu^{(1)}_1 \varepsilon^{(1)}_1)]^2 + D^1 \left[ 2 \varepsilon^{(1)}_1 \mu^{(1)}_1 \right] - 1,
\end{align*}
\]

where

\[
\begin{align*}
(D^{(1)})^2 &= \left[ \varepsilon^{(1)}_1 (\varepsilon^{(1)}_1 - \varepsilon^{(1)}_1 k^2 - 4 \mu^{(1)}_1 \varepsilon^{(1)}_1) \mu^{(1)}_1 k^2 \\
&\quad + \varepsilon^{(1)}_1 \mu^{(1)}_1 \varepsilon^{(1)}_1 \varepsilon^{(1)}_1 \mu^{(1)}_1 \mu^{(1)}_1 \Omega^2 k^2 \\
&\quad + 4 \Omega^2 [\mu^{(1)}_1 \varepsilon^{(1)}_1 \mu^{(1)}_1 \varepsilon^{(1)}_1 \mu^{(1)}_1] \right]^2.
\end{align*}
\]
PBGs with the same labels are clearly different. This means that for oblique incidence this structure displays a strong selectivity between LH and RH polarized light. For example, for LH circular polarized light, the first gap appears around $\Omega D/2\pi = 0.33$, corresponding to a wavelength $\lambda = 0.7 \ \mu$m, whereas for RH circular polarization there is practically no gap. Experimentally this should be easy to verify.

The dependencies of the normalized PBG bandwidths $\Delta\Omega^{(a)} D/2\pi$ with respect to the normalized wave number $k_D/2\pi$ are presented in Fig. 4. The absolute values of the three lowest PBG bandwidths for the LH and RH polarized EMWs are summarized in Table I. It should be mentioned that all PBGs shift upward with increasing $k_D$.

Clearly, Figs. 2–4 demonstrate an asymmetry between PBGs for LH and RH polarized eigenwaves in the chosen BG MPC. This asymmetry can be traced to the off-diagonal elements in the permittivity and the permeability tensors of YIG. Another contribution of these off-diagonal elements is the orientational dependence of the bandwidths of PBGs. On applying an external magnetic field it is possible to change the magnetization orientation in comparison with that in Fig. 1. This leads to modifications of the PBG structure, and as a result, it would be possible to tune the optical properties of MPCs with a dc magnetic field. This magnetization dependence may be used to design polarization selective tunable MO filters.

The aforementioned features of the EMW spectra can be validated by measurements of stop bands in the transmission and reflection spectra of BG MPCs, similar to calculations of transmission and reflection in BG multilayers.\(^4\)\(^9\)\(^20\)

In conclusion, the demonstrated differences in the behavior of PBGs for LH and RH polarized EMWs may play an important role for the design of magneto-photonic devices and circuits.
