Keywords: functional programming, model-based testing, validation
tools, quality of specifications

Abstract—In model-based testing the behavior of a system
under test is compared automatically with the behavior of a
model. A significant fraction of issues found in testing appear
to be caused by mistakes in the model. In order to ensure that
it prescribes the desired behavior, it has to be validated by
a human. In this work we describe a tool, esmViz, to support
this validation. Models are given in a pure, lazy functional pro-
gramming language. esmViz provides an interactive simulator
of the model, as well as diagrams of the observed behavior. The
tool is built on the eTask toolkit which results in an extremely
concise GUI definition. Experiments show that esmViz helps to
gain understanding of a model and to detect and remedy errors.

I. INTRODUCTION

In model-based testing the behavior of a system under test, sut, is compared automatically with the behavior of its specification.
Examples of model-based test tools are G*st [5], QuickCheck
[2], TorX [9], T-Uppaal [7]. The specification is a possibly non-
deterministic state transition system used as model in the tests. The
number of states, inputs and outputs can be infinite. The sut is
assumed to be a state transition system with a hidden state. One
can only apply inputs to the system and observe the corresponding
output. Key advantages of model-based test tools are the significant
reduction of the amount of manual testing; increase of test speed due
to automation; and reuse of specifications for regression testing.

Model-based test systems execute a finite number of traces. For
each trace the sut and the specification start in their initial state. An
input is selected that is covered by the specification, it is applied
to the sut, and the allowed states of the specification are computed.
If, during this process, the test system discovers that no states are
reachable for the specification, then the sut has shown behavior that
is not covered by the specification. In test jargon it is said that an
issue is found.

Ideally, each issue indicates an error in the sut. However, in
practice a significant fraction of issues appear to be caused by
problems with the specification: it does not correctly capture the
intentions of the users and the sut does something different. Even
though the fraction of issues depends on a lot on factors such as the
kind of system and the effort spent in creating the model, we estimate
that the specification has to be blamed for about 25% of the issues.

Incorrect specifications are a problem for several reasons. First,
if an issue is found it is not clear whether we have to blame the
specification or the sut. Finding and correcting errors in the
specification takes time during the test phase of the project. Second,
errors in the specification are only found during model based testing if
the behavior of the sut differs from the specified behavior. Third, any
change in the specification during the testing phase can cause major
implementation changes to the sut. Finally, any change in model or
sut invalidates in principle all previous test results. Hence, errors in
the specification can be very expensive and it is worthwhile to invest
effort to ensure its quality.

In the model-based test system G*st the pure, lazy functional
language Clean serves as specification language. Due to its high
abstraction level it is possible to write concise specifications which
contributes to their quality. It allows the test engineer to model arbi-
trarily large state, input, and output domains exactly as desired. The
advantages have been presented earlier ([4], [6]). The Clean compiler
checks quality aspects like type correctness and consistent definition
of used identifiers. Other quality aspects such as the reachability
of states, determinism and completeness, and the preservation of
constraints can be checked by systematic testing [7].

The use of a high level specification language does not rule out the
possibility that the specification prescribes the wrong behavior in a
consistent way. Hence, these kinds of errors can not be found by the
above mentioned techniques. In order to ensure that the specification
prescribes the desired behavior, it has to be validated by a human. In
this work we introduce the tool esmViz to support validation of G*st
models. This simulator enables the user to execute the specification.
Such an interactive execution appears to be more illustrative than
reviewing the specification. Second, it is possible to record the traces
of the specification executed in the simulator. The states visited and
their transitions can be visualized in an expanded state transition
diagram. Since the type of states, inputs and outputs can be infinite
and different in each and every specification, doing this conveniently
is not straightforward. The key to the solution is to use generic
definitions such that operations on these types can be derived instead
of defined manually.

The layout of the paper is as follows: in Sect. II we introduce
the concepts and notation that will be used throughout this paper. In
Sect. III we discuss the issues that arise when testing against a formal
specification. In Sect. IV we describe esmViz. Its implementation
is discussed in Sect. V. Related work is discussed in Sect. VI. We
present user experiences in Sect. VII, and conclude in Sect. VIII.

II. MODEL-BASED TESTING

In model-based testing the test tool compares the observed behavior
of the system under test, sut, with the model in order to judge the
correctness of the behavior. Any deviation of the observed behavior
of the sut from the behavior allowed by the model is called an issue.
In this section we review the models used by the model-based test
tool G*st.

The models used by G*st for testing state based systems are
extended state systems, ESMs. An ESM consists of some initial state
so and a set of transitions of the form $s \xrightarrow{i/o} t$. In such a transition $s$ is the source state, $i$ is the input triggering this transition, $o$ is the output of the system associated with this state and input, and $t$ is the target state of the system. The sets of possible states $S$, possible inputs $I$, and possible outputs $O$ of the ESM can all be infinite. The $i/o$ combination is also called the label of the transition from $s$ to $t$.

A trace $s \xrightarrow{} t$ is a sequence of labels. The empty trace contains no labels. If we have a trace $s \xrightarrow{} t$ and a transition $t \xrightarrow{i/o} u$ we can construct the trace $s \xrightarrow{} s \xrightarrow{} t \xrightarrow{i/o} u$. If we are not interested in the target state, we will occasionally write $s \xrightarrow{i/o} t$ and $s \xrightarrow{} t$ instead of a single state by taking the union of the set members.

The init of a state $s$ is the set of inputs $i$, such that there is an output $o$ and target state $t$ in the ESM such that there exists a transition $s \xrightarrow{i/o} t$. The after of a state $s$ is the set of possible target states $t$, reachable after the given trace $\sigma : s \xrightarrow{} \sigma \equiv \{t | s \xrightarrow{} \sigma \implies t\}$.

We overload traces, init, and after for sets of states instead of a single state by taking the union of the set members.

### A. Conformance

In model-based testing we try to determine conformance of the sut and the model called spec. The sut is assumed to be a transition system, but treated as a black box: one can observe its traces, but not its internal state. During tests, all observed traces of the sut have to be traces of the specification to say that the sut conforms to the specification. Formally, this relation is defined as:

$$\text{sut conf spec } \equiv \forall \sigma \in \text{traces}_{\text{spec}}(s_0), \forall i \in \text{init}(s_0) \text{ after spec } \sigma, \forall o \in O, (t_0 \text{ after } \sigma) \xrightarrow{i/o} (s_0 \text{ after spec } \sigma) \xrightarrow{i/o}$$

Here $s_0$ is the initial state of spec, and $t_0$ the initial state of sut. Intuitively the conformance relation reads: if the specification allows input $i$ after trace $\sigma$, then the observed output of the sut should be allowed by the specification. If spec does not specify a transition for the current state and input, anything is allowed. Because the sut is a black box, its initial state $t_0$ is generally not know explicitly. We assume that the sut is in this abstract state when we switch it on, or we reset it.

Limiting the applied inputs to the init of the states of the current traces allows for partial specifications spec.

### B. Testing Conformance

The conformance relation defined above covers all traces. Most interesting systems contain cycles, so traces can become infinitely long. Due to the possible infinite types for input and output, there can be even infinitely many traces of finite length. It is clear that in general a test system cannot prove conformance by executing tests. The test system $G_{\text{test}}$ approximates the conformance of the sut to the model by executing a finite number of traces of finite length.

To increase efficiency the test system records the set of allowed states, $s_0$ after $\sigma$, rather than the trace $\sigma$. If at some point in the test this set of states becomes empty we have found an issue: a trace that shows that there is no conformance between sut and the model. Clearly this way of testing is sound, each trace leading to an issue during testing shows that there is no conformance between the sut and the model. This way of model-based testing is also complete, if there is no conformance between sut and the model, there are one or more traces indicating this. Such a trace can be found by testing (if the allowed length during testing is sufficiently large).

### C. Representation of the transitions

To represent the ESM in the model-based test tool $G_{\text{test}}$ we need a finite (preferably small) and flexible representation, even if the set of transitions is infinite. Furthermore it should be easy to determine the init of the set of actual states, or to determine if an input is in this set, since this information is needed before we can apply an input during model based testing. The crucial step is to use a function to model the transitions rather than a data structure containing individual transitions. Each function alternative with variables in its patterns captures a family of related transitions. As usual lists represent sets. To define init easily we use specifications of type $S \times I \rightarrow \text{Trans } O$.

A basic assumption in $G_{\text{test}}$ is that a transition always contains a sequence (list) of output symbols. This gives some additional flexibility as well as a suitable notation for no output (the empty list). Usually it is most convenient to specify the sequence of outputs and the target state in a transition. However, the number of allowed output sequences for one input can get huge, which makes it infeasible to state them explicitly. For instance in an authentication procedure a typical step is to ask for a challenge (the input), the response is a 64 bit number. Listing all possible outputs and target states explicitly requires $2^{64}$ transitions. In such a situation we prefer one function of type $[O] \rightarrow [S]$ rather than all individual transitions. Here the list of states as result has the usual meaning: all states (zero or more) that correspond to the given output sequence. Again, a single function captures a family of related transitions. In Clean these types are:

$$:: \text{Spec s i o} : s \rightarrow (\text{Trans } o s)$$

Note that we use type parameters to allow any concrete type to be used for state (s), input (i), and output (o).

#### 1) Example:

As an example specification we show the model of a beverage vending machine that supplies coffee and tea (see Fig. 1). Initially the machine is in a state called Off. After the input $\text{SwitchOn}$ it enters state On, if it receives a product. If there is enough money the user gets his product and the value of the counter is decreased accordingly. The types used in this model are:

```clean
:: Money := Int
:: State = Off | On Money
:: Input = SwitchOn | SwitchOff
:: Coin Money | Butt Product
:: Product = Coffee | Tea
:: Output = Cup Product | Return Money
```

A possible specification is given as the function $v\text{spec}$ below. We deliberately introduce some errors and strange transitions in this specification, later we return to it in an attempt to find these problems.

```clean
vSpec :: !State !Input -> !Trans Output State
vSpec Off SwitchOn = [Pt [Off] [On 0]]
```

```clean
vSpec Off SwitchOn = [Pt [Off] [On 0]]
```

```clean
vSpec (On s) (Coin c)
```

```clean
// condition should be s+c<Max
// s<Max = [Pt [On (s+c)]]
// output should be Return c
```
In this section we describe the web browser-based simulation tool, esmViz, that we have created to determine the quality of specifications. The tool also gives an impression of the behavior specified by the model, and checks user defined predicates on the transitions encountered. Simulation is useful to give non-experts a good impression of the specified behavior. The GUI of esmViz is a screen with the following elements (Fig. 2(a)): 1. A list of found issues. The list is empty in Fig. 2(a). 2. The explored model as the state space is discovered step-by-step with individual transitions. This requires a thorough observation of the shown behavior. Since the state space is discovered step-by-step by the user, the chances of finding the problems are quite good. Each of the above methods can in principle find problems in the specification, but none of them can guaranteed this. Each method either requires human spotting of problems, or human formulation of properties revealing the problems. In the remainder we describe esmViz. It combines model-checking of properties on transitions with validation by step-wise simulation. Together with GVst, this covers a broad range of tools to investigate the quality of models.

### III. ISSUES FOUND IN MODEL BASED TESTING

Issues are traces that show that there is no conformance between the sut and the specification. Ideally each issue found indicates an error (bug) in the sut, but that is not always the case. Other sources of issues are inaccuracies in the model, problems in the interface between the test system and the sut, and internal faults in the test tool. One wishes to eliminate these other sources of issues before actual testing starts.

In ordinary automatic testing the test tool executes a manually specified or recorded trace. As a rule of thumb test engineers say that 40% of the issues found indicate errors in the sut, but that is not always the case. Other sources of issues are inaccuracies in the model, problems in the interface between the test system and the sut, and internal faults in the test tool. One wishes to eliminate these other sources of issues before actual testing starts.

In model-based testing the traces are generated automatically and on-the-fly from the specification. This guarantees that the traces used during the tests always correspond to the current version of the specification, but that is not always the case. Other sources of issues are inaccuracies in the model, problems in the interface between the test system and the sut, and internal faults in the test tool. One wishes to eliminate these other sources of issues before actual testing starts.

A. The ESM description

Each problem detected is reported as a nonempty list of strings. The ESM description between state s and state t, and has label of string (or set of strings) on the edge. The output sequences to be used when esmViz encounters a transition is rendered as an arrow between state s and state t, and has label i/o at its edge.

B. Example

Here is the beverage vending machine esm specification:

```
vendingESM :: ESM State Input Output
vendingESM = { s_0 = Off, d_F = vspec, out = undef, pred = healthy }
```

The ESM has length 4.6. Finally, a legend that tells what the elements of the rendering are.

The tool esmViz creates an ESD of the behavior encountered during simulation which is rendered as a directed graph. In ESM diagrams a parameterized state is drawn as one state, in the ESD a state is created for each value of the parameters encountered during simulation. In the beverage vending machine example the states (On 10) and (On 20) are different in the ESD, but they are one state in the ESM (Fig. 1). A transition \( s \xrightarrow{i/o} t \) is rendered as an arrow between state s and state t, and has label i/o at its edge.

A. The ESM description

The ESD is created by esmViz based on an ESM and instances of generic functions used for instance to display and compare values of the data types used for states \( S \), input \( I \) and output \( O \). The ESM as described in Sec. II is a Clean value of type \((ESM S I O)\):

```
:: ESM s i o = { s_0 :: s , d_F :: Spec s i o , out :: s i \rightarrow \{o\} , pred :: (SeeTrans s i o) \rightarrow \{String\} }:: SeeTrans s i o ::= (s,i,o)
```

Field \( s_0 \) is \( s_0 \), and \( d_F \) is \( \delta_F \). The function \( out \) is needed to generate the output sequences to be used when \( esmViz \) encounters a transition of type \( \{o\} \rightarrow \{s\} \). If such transitions can not occur in the used specification, this field can be undefined. Field \( pred \) is a predicate over the transitions seen during simulation as discussed in Sect. III. Each problem detected is reported as a nonempty list of strings.

While exploring \( esm \), the tool collects all visited states, transitions and issues. This results in a partially known automaton, and is captured concisely with the following type:

```
:: KnownAutomaton s i o = { trans :: [ SeeTrans s i o ] , issues :: [(SeeTrans s i o,String)] } Encountered states can be extracted easily from the seen transitions and are not recorded separately. Transitions that correspond to an issue are drawn in red.
```

The tool \( esmViz \) also indicates the transitions that are part of the current traces. For a nondeterministic specification there can be multiple traces active. We record this as a list of transitions that is possible in each step of the trace.

```
:: Trace s i o ::= \{ SeeTrans s i o \}
```

Trace transitions are drawn in blue with larger arrowheads.

For implementation reasons it is convenient to record the set of active states. For a nonempty trace these are exactly the states in the after set of the current traces. Let this set after \( k \) steps be \( S_k \). Each state in \( S_k \) is rendered with a red interior. States are displayed as circles, where \( esm.s_0 \) has a double border. Initially, \( S_0 = \{esm.s_0\} \).

The user can choose one input of \( init(S_k) \), which is the set of all possible inputs. This set of inputs is empty for a final state. The number of possible inputs is limited (by default 50). Given a concrete choice \( i \in init(S_k) \), \( esmViz \) adds all transitions from the current states that correspond to this input. For transition specified by \( \{o\} \rightarrow \{s\} \), the function \( esm.out \) is used to determine the outputs and target states of transitions. If the target states of these transitions exist the arrows go to the existing states, otherwise the states are added to the ESD. If the transitions are already in the ESD, they just have to be painted red, otherwise they are added. The new transitions are also added to the traces, and the existing part of the trace is pruned to reflect the new extensions. The set of new states \( S_{k+1} \) is computed with \( S_{k+1} = \{s \in S_k | s \xrightarrow{i/o} t \in \delta_F \} \).

The system determines for each known state whether the user has ‘discovered’ all outgoing edges, i.e. all edges with \( i \) in the init of that state. In that case, the state is rendered with a blue interior instead of a light grey default one. This provides a strong clue which part of \( esm \) has been fully explored.

Pressing the button labeled Back removes the last transition from each trace. The known automaton is not affected by going back in the trace. The browser’s back button acts as undo action. With the Add all button all transitions leaving from the current states are added. These transitions are not added to the trace, nor effect \( S_k \). Using an integer edit field, adding transitions can be done recursively \( n \) steps deep. Pressing Prune removes all transitions and associated issues that do not belong to the current trace. The Reset button brings the \( esmViz \) tool in its initial state, only the state \( s_0 \) is displayed. The trace can be removed by the button Clear trace, the states and transitions in the ESD are not effected by this action.

The current state can be changed by clicking on a state in the diagram. If this state is part of the trace or reachable from an active state in one step the trace will be adapted accordingly, otherwise a new trace starts at that node.

B. Example

Here is the beverage vending machine \( esm \) specification:

```
vendingESM :: ESM State Input Output
vendingESM = { s_0 = Off, d_F = vspec, out = undef, pred = healthy }
```

Fig. 2. (a) The validation tool in action with the beverage vending machine case. (b) ESD showing some of the issues in the beverage vending machine.
where healthy checks p1 \dashv p3 (Sect. III). An ESD showing all issuesdiscribed by healthy is depicted in Fig. 2(b).

healthy :: (SeenTrans, State, Input, Output) \rightarrow [[String]]
healthy (s,i,o,t) = [if (vs+vi \not\dashv vo+vt) // value preservation in transition? (p1)
  ["value is not preserved in this transition, ", "value is preserved in this transition. " as vs=vi]
  , and value o+value t =\dashv .toString (vo+vt)]
  , if (vt>Max) // value of target state within bound? (p2)
  ["Value of target state " .toString vt " larger than Max. "."]
  , case (i.o) of // obtained the ordered product? (p3)
    (Butt p,[Opx q]) | p =\not= q
      = ["The required product is unequal* .", to the delivered product!*]
      = []
  ]
where vs = value s; vi = value i
vo = value o; vt = value t

V. IMPLEMENTATION

The esmViz tool has been written in Clean, using the iTask toolkit [8]. Despite its conciseness (800 loc) it offers a fair amount of functionality (see also other tools in Sect. VI). In this section we present the most interesting parts of the implementation. These are the main structure of the GUI (Sect. V-A) and the integration of the ESD rendering tool GraphViz [3] that we used in the application (Sect. V-B).

A. The Main GUI Structure: Iterating iTasks

The main GUI structure of esmViz is an iteration of the main tool task function DiGraphFlow. As discussed in Sect. IV, it provides the user with a number of elements, expressed as a list of choices (the arguments of orTaskL below which folds the basic iTask - | | - choice user with a number of elements, expressed as a list of choices (the task function DiGraphFlow. As discussed in Sect. IV, it provides the

\[
\text{DiGraphFlow} (ka,as,trace,n) = \text{orTaskL}
\]
\[
\text{issuesToHtml ka.issues !>> state}
\]
\[
\text{.chooseTaskV (sortBy (\lambda(a,_) (b,_) a\langle b})
\]
\[
\text{([render i,step i) \backslash i \rightarrow \text{possibleInputs esm as})}
\]
\[
\text{.chooseTask}
\]
\[
\text{["Back", back)
\]
\[
\text{("Prune", prune)
\]
\[
\text{("Reset", return_V (newKA,[esm,s_0,\{\},n])
\]
\[
\text{("Clear trace", return_V (ka,as,\{\},n))}
\]
\[
\text{.stepN \text{traceHtmlTable trace \text{label1}}}
\]

Note the correspondence between this definition and the GUI as displayed in Fig. 2(a). The list of found issues are displayed before the ESD editor (line 3); the possible inputs init S_0 are defined in lines 4-5; the navigation commands are summarized in lines 6-11; and finally, the trace and legend are displayed in line 11. The state task is given below:

state = editTask "OK"

mDiGraphThisExe

\[
\text{\Rightarrow Adig \rightarrow let}
\]
\[
\text{\Rightarrow dig \rightarrow let}
\]
\[
\text{ax \rightarrow let}
\]
\[
\text{in return_V (ka,as,\text{trace'}n)
\]

The iTask editTask l v creator combines an editor with initial value v with which users can create new values of the same type as v’s type. When the button labeled with l has been pressed, then the new value is returned by this editor and the task is done. As discussed in Sect. IV, the user can select a new state. For reasons of space, we do not show the code of the other functions.

B. The Rendering of the Explored Automaton

By far the most intricate component of the GUI is the ESD editor. Creating attractive renderings of directed graphs is known to be a hard problem. Fortunately, we can rely on other tools to solve this problem. Here we have used the Graphviz tool set [3]. Directed graphs are described using the DOT language. Given a DOT text file, the dot tool can be invoked to create a rendering in various formats (we will use the gif output). Note that this interface is text-based, whereas editors in the iTask toolkit are type based. We can embed the text based tools of GraphViz in the type based iTask toolkit in a compositional way by defining a suitable collection of data types that describe an ESD as a directed graph. This collection of data types captures the DOT language. The relevant top level type definitions are:

\[
\text{:: Digraph = Digraph String [GraphAttribute]}
\]
\[
\text{:: NodeDef = NodeDef Int [NodeAttribute] [EdgeAttribute]}
\]
\[
\text{:: EdgeDef :== (Int,[EdgeAttribute])}
\]
\[
\text{:: SelectedItem = Node Int}
\]

A (Digraph name atts nodes item) value represents a directed graph. A directed graph has nodes, each of which is identified by a number, and is connected with other nodes by means of edges. Graphs, nodes, and edges have attributes. GraphViz supports an extensive set of attributes (almost 150) that can be used to alter and tweak the output. In DOT, attributes are specified as name = value pairs. Some attributes are shared by graphs, nodes, and edges. We have represented attributes separately for graphs, nodes, and edges, each as a list of unary data constructors. For instance, for graph attributes we have Get_name value pairs. A single generic function prints these values as correct DOT expressions. The result is that we have both a typed representation of DOT expressions (Digraph values) as well as a textual representation (printing such a value with toString). The function mDiGraph yields the Digraph value that represents the currently explored ESD.

The iTask editor for Digraph values performs the following actions for a d :: Digraph value identified by name. First, compute e = toString d and save e in file name.dot. Second, invoke dot on name.dot, which yields a rendering as name.gif. Third, invoke dot to create a name.map file to allow the user to select states. Fourth, alter the lines in name.map to invoke a script that sends the label of the selected state to the server application. Finally, generate the proper HTML to be included in the application page. The server application, when receiving the label of a selected state, updates the corresponding Digraph value to reflect the change. Now the application continues with the new Digraph value.

VI. RELATED WORK

The mCRL2 tool set [7], [7] uses a process algebraic specification language, mCRL2 [7], to describe distributed, communicating systems. It has a functional style data language with recursive types, data constructors, functions, lambda-abstraction, and structured data. It comes with an extensive number of tools (15) for analysis purposes. Five are relevant to our work: with xsim a user can explore a linearized mCRL2 specification in a similar way as with our tool, using a GUI (the simulation tool sim has a command line interface); the user can select actions, after which the tool shows the resulting state. Besides interactively exploring the mCRL2 specification, the tool set also allows to render the complete state space: NoodleView (for 2D rendering) and FSMView (for 3D rendering). Before this is possible, the state space needs to be generated with lps2lts.
The TorX tool set [9], [2] is a model based test tool to check conformance of real suts, based on the ioco theory of testing. The specification is a Labeled Transition System (LTS), or one that is derived from a higher level specification language that converts to LTS (e.g. mCRL2 described above). The tool uses the specification to automatically determine inputs, observe outputs from the sut, and make a final verdict. In this sense, it is not useful for exploring a specification. However, once a test run has been created, the user can explore the actual trace which is depicted as a message sequence chart.

The Uppaal tool set [1], [7] can be used for both validation and verification (using model checking) of time-based systems. Validation is done by means of a graphical simulator of a time-based automaton specification. The automaton specification is basically a labeled transition system with timing constraints. Uppaal allows for simple data types, clocks, and constraints on these clocks. The user can create specifications in an intuitive, graphical way. The user can stepwise direct the system’s behavior, or generate a random trace.

The esmViz tool differs with the mCRL2 approach in that we use a single modeling formalism. Except for the 3D rendering all of the functionality of the mCRL2 tool set is available in esmViz. The TorX tool set is really a model based testing harness, and is less suited for exploration purposes. Specifications within Uppaal can be created graphically. In esmViz specifications are given as a function, out of which a graphical approximation is ‘discovered’ by the user or by the system. In our opinion this combines the best of both worlds: the succinctness of functional programming with the intuitive appeal of a graphical rendering.

VII. EXPERIENCES

In order to judge the quality of esmViz 10 master students in computer science studied some test cases with and without esmViz. These students are literate Clean programmers, have a basic understanding of model-based testing with G\textsuperscript{Vst} and the specifications needed (but no hands-on experience). After an introduction to esmViz and playing with an example similar to the beverage vending machine in this paper the students were asked to locate problems in two other case studies. The examples were heavily parameterized specifications of a number guessing game and a telephone number database that contains potentially over one million states. Drawing all these states makes finding the problems only harder. The errors in the specification can however all be found by traces of about ten to twenty transitions.

The students found esmViz very handy to get a feeling for the behavior of the specified system. Everybody found it much easier to understand a specified system with the tool than without. Finding errors in the specification by simulation remains hard, but the tool makes it easier. The same holds for finding the source of issues found by G\textsuperscript{Vst}. This is consistent with the general observation in all kinds of testing: finding issues is one thing, but finding their cause is another.

VIII. CONCLUSIONS

There are two kinds of conclusions from the work described in this paper. First, the specification simulator esmViz described in this paper really helps a lot to understand the behavior of the extended state machines used as specification in model-based testing. Although the compiler of the statically typed functional programming language used as carrier of these specifications checks the models, the models can still contain errors. Finding these semantical errors is hard. The simulator helps in locating these problems, especially if an appropriate constraint on transitions or states is known. Second, implementing such a tool with iTasks is a real pleasure. Integrating Graphviz with iTasks turned out to be smooth. Implementing a browser interface for esmViz using the iTask system imposes some restrictions on the layout of the GUI, but works well. The different possible user actions are modeled each by an iTask. The iTask system is well suited to compose these tasks in a flexible way and takes care of rendering them.
