Validating Specifications for Model-Based Testing

Submit to SERP 2008

I. INTRODUCTION

In model-based testing the behavior of a system under test, SUT, is compared automatically with the behavior of a model. A significant fraction of issues found in testing appear to be caused by mistakes in the model. In order to ensure that it prescribes the desired behavior, it has to be validated by a human. In this work we describe a tool, esmViz, to support this validation. Models are given in a pure, lazy functional programming language. esmViz provides an interactive simulator of the model, as well as diagrams of the observed behavior. The tool is built on the iTask toolkit which results in an extremely concise GUI definition. Experiments show that esmViz helps to gain understanding of the model and to detect and remedy errors.

II. MODEL-BASED TESTING

In model-based testing the test tool compares the observed behavior of the system under test, SUT, with the model in order to judge the correctness of the behavior. Any deviation of the observed behavior from the behavior allowed by the model is called an issue. In this section we review the models used by the model-based test tool GVst.

The models used by GVst for testing state based systems are extended state systems, ESMs. An ESM consists of some initial state that the behavior of the SUT differs from the specified behavior. Third, any change in the specification during the testing phase can cause major implementation changes to the SUT. Finally, any change in model or SUT invalidates in principle all previous test results. Hence, errors in the specification can be very expensive and it is worthwhile to invest effort to ensure its quality.

In the model-based test system GVst the pure, lazy functional language Clean serves as specification language. Due to its high abstraction level it is possible to write concise specifications which contributes to their quality. It allows the test engineer to model arbitrarily large state, input, and output domains exactly as desired. The advantages have been presented earlier ([4], [6]). The Clean compiler checks quality aspects like type correctness and consistent definition of used identifiers. Other quality aspects such as the reachability of states, determinism and completeness, and the preservation of constraints can be checked by systematic testing ([7]).

The use of a high level specification language does not rule out the possibility that the specification prescribes the wrong behavior in a consistent way. Hence, these kinds of errors can not be found by the above mentioned techniques. In order to ensure that the specification prescribes the desired behavior, it has to be validated by a human. In this work we introduce the tool esmViz to support validation of GVst models. This simulator enables the user to execute the specification. Such an interactive execution appears to be more illustrative than reviewing the specification. Second, it is possible to record the traces of the specification executed in the simulator. The states visited and their transitions can be visualized in an expanded state transition diagram. Since the type of states, inputs and outputs can be infinite and different in each and every specification, doing this conveniently is not straightforward. The key to the solution is to use generic definitions such that operations on these types can be derived instead of defined manually.

The layout of the paper is as follows: in Sect. II we introduce the concepts and notation that will be used throughout this paper. In Sect. III we discuss the issues that arise when testing against a formal specification. In Sect. IV we describe esmViz. Its implementation is discussed in Sect. V. Related work is discussed in Sect. VI. We present user experiences in Sect. VII, and conclude in Sect. VIII.
A. Conformance

Clearly this way of testing is the model by executing a finite number of traces of finite length. or more traces indicating this. Such a trace can be found by testing this set of states becomes empty we have found an

\( m \rightarrow t \) a sequence of labels. The empty trace contains no labels. If we have a trace \( m \rightarrow t \) and a transition \( t \rightarrow u \) we can construct the trace \( m \rightarrow t \rightarrow u \). If we are not interested in the target state, we will occasionally write \( m \rightarrow t \equiv \exists s. s \rightarrow t \) and \( s \rightarrow t \equiv \exists \sigma. s \rightarrow t \). All traces from a given state are defined as:

\( \text{traces}(s) \equiv \{ \sigma | s \rightarrow t \} \). The init of a state \( s \) is the set of inputs \( i \), such that there is an output \( o \) and target state \( t \) in the ESM such that there exists a transition \( s \rightarrow t \). The after of a state \( s \) is the set of possible target states \( t \), reachable after the given trace \( \sigma: s \rightarrow t \). We overload traces, init, and after for sets of states instead of a single state by taking the union of the set members.

A. Conformance

In model-based testing we try to determine conformance of the sut and the model called spec. The sut is assumed to be a transition system, but treated as a black box: one can observe its traces, but not its internal state. During tests, all observed traces of the sut have to be traces of the specification to say that the sut conforms to the specification. Formally, this relation is defined as:

\[ \text{sut} \, \text{conf} \, \text{spec} \equiv \forall s \in \text{traces}_{\text{spec}}(s_0), \]

\[ \forall i \in \text{init}(s_0) \, \text{after}_{\text{spec}}(s), \]

\[ \forall o \in O, \]

\[ (t_0 \, \text{after}_{\text{spec}}(s) \rightarrow i/o \rightarrow (s_0 \, \text{after}_{\text{spec}}(s)) \rightarrow i/o). \]

Here \( s_0 \) is the initial state of spec, and \( t_0 \) the initial state of sut. Intuitively the conformance relation reads: if the specification allows input \( i \) after trace \( \sigma \), then the observed output of the sut should be allowed by the specification. If spec does not specify a transition for the current state and input, anything is allowed. Because the sut is a black box, its initial state \( t_0 \) is generally not know explicitly. We assume that the sut is in this abstract state when we switch it on, or we reset it.

Limiting the applied inputs to the init of the states of the current traces allows for partial specifications spec.

B. Testing Conformance

The conformance relation defined above covers all traces. Most interesting systems contain cycles, so traces can become infinitely long. Due to the possible infinite types for input and output, there can be even infinitely many traces of finite length. It is clear that in general a test system cannot prove conformance by executing tests. The test system Guvi approximates the conformance of the sut to the model by executing a finite number of traces of finite length.

To increase efficiency the test system records the set of allowed states, \( s_0 \, \text{after}_{\sigma} \), rather than the trace \( \sigma \). If at some point in the test this set of states becomes empty we have found an issue: a trace that shows that there is no conformance between sut and the model. Clearly this way of testing is sound, each trace leading to an issue during testing shows that there is no conformance between the set and the model. This way of model-based testing is also complete, if there is no conformance between sut and the model, there are one or more traces indicating this. Such a trace can be found by testing (if the allowed length during testing is sufficiently large).

C. Representation of the transitions

To represent the ESM in the model-based test tool Guvi we need a finite (preferably small) and flexible representation, even if the set of transitions is infinite. Furthermore it should be easy to determine the init of the set of actual states, or to determine if an input is in this set, since this information is needed before we can apply an input during model based testing. The crucial step is to use a function to model the transitions rather than a data structure containing individual transitions. Each function alternative with variables in its patterns captures a family of related transitions. As usual lists represent sets. To define init easily we use specifications of type \( S \times I \rightarrow \text{Trans} \rightarrow O \).

A basic assumption in Guvi is that a transition always contains a sequence (list) of output symbols. This gives some additional flexibility as well as a suitable notation for no output (the empty list).

Usually it is most convenient to specify the sequence of outputs and the target state in a transition. However, the number of allowed output sequences for one input can get huge, which makes it infeasible to state them explicitly. For instance in an authentication procedure a typical step is to ask for a challenge (the input), the response is a 64 bit number. Listing all possible outputs and target states explicitly requires \( 2^{64} \) transitions. In such a situation we prefer one function of type \( \text{Trans} \rightarrow \text{Output} \) rather than all individual transitions. Here the list of states as result has the usual meaning: all states (zero or more) that correspond to the given output sequence. Again, a single function captures a family of related transitions. In Clean these types are:

\[ \text{spec} \, s \, i \, o \equiv s \rightarrow \{ \text{Trans} \rightarrow o \} \]

\[ \text{trans} \, o \rightarrow s = \text{Pt} \, s \, i \rightarrow \text{Pt} \, \{ o \rightarrow s \} \]

Note that we use type parameters to allow any concrete type to be used for state (s), input (i), and output (o).

1) Example: As an example specification we show the model of a beverage vending machine that supplies coffee and tea (see Fig. 1). Initially the machine is in a state called Off. After the input SwitchOn

\[ \text{spec} \, s \, i \, o \equiv \{ s \rightarrow \{ \text{Trans} \rightarrow o \} \} \]

The intented specification of the beverage vending machine

\[ \text{spec} \, s \, i \, o \equiv \{ s \rightarrow \{ \text{Trans} \rightarrow o \} \} \]

it enters state On 0 without producing any output. The integer in this state is used to record the amount of money inserted. Now the user can either insert a coin with a value given as parameter as long as the counter in the state remains less than Max, or press a button to receive a product. If there is enough money the user gets his product and the value of the counter is decreased accordingly. The types used in this model are:

\[ :: \text{Money} \equiv \text{Int} \]

\[ :: \text{State} = \text{Off} | \text{On} \text{Money} \]

\[ :: \text{Input} = \text{SwitchOn} | \text{SwitchOff} \]

\[ :: \text{Product} = \text{Coffee} | \text{Tea} \]

\[ :: \text{Output} = \text{Get} \text{Product} | \text{Return} \text{Money} \]

A possible specification is given as the function \( \text{vSpec} \) below. We deliberately introduce some errors and strange transitions in this specification, later we return to it in an attempt to find these problems.

\[ :: \text{spec} \equiv \{ \text{State} \rightarrow \{ \text{Trans} \rightarrow \text{Output} \} \} \]

\[ \text{vSpec} \equiv \{ \text{Spec} \rightarrow \{ \text{Trans} \rightarrow \text{Output} \} \} \]

\[ \text{vSpec} \equiv \{ \text{Spec} \rightarrow \{ \text{Trans} \rightarrow \text{Output} \} \} \]

// condition should be s<Max

\[ s<Max \equiv \{ \text{Spec} \rightarrow \{ \text{Trans} \rightarrow \text{Output} \} \} \]

// output should be Return
vSpec state input = [ ]  

// pattern should be (Butt Coffee) 
vSpec (On s) (Butt coffee) 
| s>20 = [Pt [Cup Coffee] (On (s-20)), Pt [] (On s)]  
| we get Coffee instead of Tea 
| s>10 = [Pt [Cup Coffee] (On (s-10))]  
// do nothing for other buttons 
vSpec (On s) (Butt p) = [Pt [] (On s)]  
// otherwise: nothing defined 

This specification is partial (e.g., the effect of pressing a product button when the machine in the state Off is not defined), and nondeterministic (if there is enough money in the machine and the user asks for coffee, the machine either produces coffee, or does nothing at all). Non-determinism models limited knowledge of the state of the real machine: e.g., if there are coffee beans it will produce coffee, otherwise it cannot produce coffee and waits for a new command.

III. ISSUES FOUND IN MODEL BASED TESTING

Issues are traces that show that there is no conformance between the sut and the specification. Ideally each issue found indicates an error (bug) in the sut, but that is not always the case. Other sources of issues are inaccuracies in the model, problems in the interface between the test system and the sut, and internal faults in the test tool. One wishes to eliminate these other sources of issues before actual testing starts.

In ordinary automatic testing the test tool executes a manually specified or recorded trace. As a rule of thumb test engineers say that 40% of the issues found indicate a real error in the sut. A tiny fraction of these issues is caused by the test tool itself, or the interface with the sut. Most issues are caused by the fact that the trace used does not correspond to the current version of the specification, or the specification itself is incorrect.

In model-based testing the traces are generated automatically and on-the-fly from the specification. This guarantees that the traces used during the tests always correspond to the current specification. As one expects this implies that a larger fraction of the issues found indicate errors in the sut. In our experience about 75% of the issues found during model-based testing indicate errors in the sut. The fraction of actual errors depends on the amount of effort spent on making a high quality specification, the quality of the informal specification and requirements used as basis, and the size and complexity of the system.

The specification is a Clean function, hence the compiler can readily check relevant properties: i) all used identifiers properly defined, ii) is the entire specification type correct, iii) are all alternatives (transitions) reachable. Still, well typed specifications can go wrong. The problems with specifications that cannot be detected by the compiler can be divided in the following classes.

1) Relevant behavior of the system is not covered in the specification. Since the test system is carefully designed to handle partial specifications, this cannot be detected. Missing parts of the behavior are not covered in the tests.

2) The specification contains design errors. Typically a family of transitions is too large or too small, or leads to the wrong target state. If the sut does a better (or at least different) job, the test system will notice the difference if an appropriate trace occurs and hence reports an issue. Consider the alternative for vSpec (On s) (Coin c) in the example of the previous section. The wrong condition and forgotten return of money if the state becomes too large are probably design errors.

3) The transitions are designed correctly, but the implementation is incorrect. A typical example is the use of lowercase identifiers (variables) where an uppercase identifier (constructor) is intended, or vice versa. Another source of problems is copy-paste programming used to define similar transitions, where not all necessary changes are made. In our example this occurs in the transitions for vSpec (On s) (Butt coffee), and vSpec (On s) (Butt Tea).

All these problems result in well typed models. If the implementation is based on such a model, it is not possible to detect the problems by testing. Nevertheless, they must be found and preferably before model-based testing starts.

Various approaches to find these kind of problems are: Inspection or reviews of the specification. Problems can be found by manual inspection of the specification. As the model tells the whole story, there is nothing that prevents these errors from being detected by reviewing the code. However, due to their subtle nature, they might be missed.

Model checking. If we have the right properties and the specification is available in a form suited for model checking, the problems can be found by model checking. Limiting factors are the availability of the model in a form suited for a particular model checker, and the availability of properties to check. If the problems are known we can often find such a set of properties quite easily, but that is too late. In our example we can require: p1) every transition preserves the amount of money, p2) the amount of money in the machine is always less then max, and p3) if we receive a product, it must be equal to the requested product. Finding a complete set of properties that reveals all problems is in general quite tricky.

Testing properties of the specification. Properties on transitions can be tested by the logical branch of G\$st. The advantage is that everything can be done within the same framework, especially the Clean specification function can be used as subject of tests. The drawback is that testing gives less certainty for large systems (although for small specifications the logical test system provides a proof by exhaustive testing).

Validation by simulation. The specification can be used as basis for an interactive simulation. With some effort the simulator not only displays the current transition, but also depicts the state space that is covered in the current simulation. Such a simulation can reveal that (important) parts of the behavior are missing, as well as problems with individual transitions. This requires a thorough observation of the shown behavior. Since the state space is discovered step-by-step by the user, the chances of finding the problems are quite good.

Each of the above methods can in principle find problems in the specification, but none of them can guaranteed this. Each method either requires human spotting of problems, or human formulation of properties revealing the problems.

In the remainder we describe \texttt{esmViz}. It combines model-checking of properties on transitions with validation by step-wise simulation. Together with \texttt{G\$st}, this covers a broad range of tools to investigate the quality of models.

IV. VALIDATION OF SPECIFICATIONS WITH \texttt{esmViz}

In this section we describe the web browser-based simulation tool \texttt{esmViz}, that we have created to determine the quality of specifications. The tool also gives an impression of the behavior specified by the model, and checks user defined predicates on the transitions encountered. Simulation is useful to give non-experts a good impression of the specified behavior. The GUI of \texttt{esmViz} is a screen with the following elements (Fig. 2(a)): 1. A list of found issues. The list is empty in Fig. 2(a). 2. The explored model as an Extended State Diagram (ESD). 3. Within the ESD the set of possible active states determines the inputs that can be given. These are enumerated as buttons that the user can press to advance the system one step. In Fig. 2(a) the active states are \( S = \{0, 20\} \), and init \((S) = \{\text{ButtCoffee}, \text{ButtTea}, \text{Coin10}, \text{Coin20}, \text{SwitchOff}\} \). 4. Commands for navigation purposes, resetting the exploration, and so on. 5. The current trace, as explained in Sect. II. Here the trace
A. The ESM description

The ESM description between state $s$ and state $t$, and has label $i/o$ at its edge.

Each problem detected is reported as a nonempty list of strings.

The output sequences to be used when $\text{esmViz}$ encounters a transition possible in each step of the trace.

Encountered states can be extracted easily from the seen transitions. For a nondeterministic specification there can be multiple traces active. We record this as a list of transitions that is captured concisely with the following type:

$$\begin{align*}
\text{ESM s i o} & = \{ \text{trans} :: [\text{SeenTrans s i o}], \text{issues} :: [(\text{SeenTrans s i o}, \text{String})] \}
\end{align*}$$

Field $s_0$ is so, and $d_F$ is $d_F \in \text{spec}$. The function $\text{out}$ is needed to generate the output sequences to be used when $\text{esmViz}$ encounters a transition of type $[o] \rightarrow [s]$. If such transitions can not occur in the used specification, this field can be undefined. Field $\text{pred}$ is a predicate over the transitions seen during simulation as discussed in Sect. III. Each problem detected is reported as a nonempty list of strings.

While exploring $\text{esm}$, the tool collects all visited states, transitions and issues. This results in a partially known automaton, and is captured concisely with the following type:

$$\begin{align*}
\text{KnownAutomaton s i o} & = \{ \text{trans} :: [\text{SeenTrans s i o}], \text{issues} :: [(\text{SeenTrans s i o}, \text{String})] \}
\end{align*}$$

Encountered states can be extracted easily from the seen transitions and are not recorded separately. Transitions that correspond to an issue are drawn in red.

The tool $\text{esmViz}$ also indicates the transitions that are part of the current traces. For a nondeterministic specification there can be multiple traces active. We record this as a list of transitions that is possible in each step of the trace.

$$\begin{align*}
\text{Trace s i o} & = \{ [\text{SeenTrans s i o}] \}
\end{align*}$$

Trace transitions are drawn in blue with larger arrowheads.

For implementation reasons it is convenient to record the set of active states. For a nonempty trace these are exactly the states in the after set of the current traces. Let this set after $k$ steps be $S_k$. Each state in $S_k$ is rendered with a red interior. States are displayed as circles, where $\text{esm.s_0}$ has a double border. Initially, $S_0 = \{ \text{esm.s_0} \}$.

The user can choose one input of $\text{init}(S_k)$, which is the set of all possible inputs. This set of inputs is empty for a final state. The number of possible inputs is limited (by default 50). Given a concrete choice $i \in \text{init}(S_k)$, $\text{esmViz}$ adds all transitions from the current states that correspond to this input. For transition specified by $F t f$ of type $[o] \rightarrow [s]$, the function $\text{esm.out}$ is used to determine the outputs and target states of transitions. If the target states of these transitions exist the arrows go to the existing states, otherwise the states are added to the ESD. If the transitions are already in the ESD, they just have to be painted red, otherwise they are added. The new transitions are also added to the traces, and the existing part of the trace is pruned to reflect the new extensions. The set of new states $S_{k+1}$ is computed with

$$S_{k+1} = \{ s | \text{exists } s \in S_k \land s \xrightarrow{i/o} t \in \text{spec} \}.$$
where healthy checks \( p_1 = p_3 \) (Sect. III). An ESD showing all issues
described by healthy is depicted in Fig. 2(b).

**healthy ::** (SeenTrans \( \text{State} \) \( \text{Input} \) \( \text{Output} \)) \( \rightarrow \) [[String]]

\[
\text{healthy} \left( s, i, o, t \right) = \begin{cases} 
1 & \text{if } \left( vs+vi = vo+vt \right) \\
\text{false} & \text{else}
\end{cases}
\]

**hs** checks \( p_1 \) (Sect. III). An ESD showing all issues described by healthy is depicted in Fig. 2(b).

**B. The Rendering of the Explored Automaton**

By far the most intricate component of the GUI is the ESD editor. Creating attractive renderings of directed graphs is known to be a hard problem. Fortunately, we can rely on other tools to solve this problem. Here we have used the Graphviz tool set [3]. Directed graphs are described using the DOT language. Given a DOT text file, the dot tool can be invoked to create a rendering in various formats (we will use the gif output). Note that this interface is text-based, whereas editors in the iTask toolkit are type-based. We can embed the text-based tools of Graphviz in the type-based iTask toolkit in a compositional way by defining a suitable collection of data types that describe an ESD as a directed graph. This collection of data types captures the DOT language. The relevant top level type definitions are:

\[
\text{:: Digraph} = \text{Digraph String [GraphAttribute]} \\
\text{:: NodeDef} = \text{NodeDef Int [NodeAttribute]} \text{[EdgeDef]} \\
\text{:: EdgeDef} = \text{[Int [EdgeAttribute]]} \\
\text{:: SelectedItem} = \text{Node Int}
\]

A Digraph name nodes item value represents a directed graph. A directed graph has nodes, each of which is identified by a number, and is connected with other nodes by means of edges. Graphs, nodes, and edges have attributes. Graphviz supports an extensive set of attributes (almost 150) that can be used to alter and tweak the output. In DOT, attributes are specified as \( name = value \) pairs. Some attributes are shared by graphs, nodes, and edges. We have represented attributes separately for graphs, nodes, and edges, each as a list of unary data constructors. For instance, for graph attributes we have Get name value pairs. A single generic function prints these values as correct DOT expressions. The result is that we have both a typed representation of DOT expressions (Digraph values) as well as a textual representation (printing such a value with toString). The function mkDigraph yields the Digraph value that represents the currently explored ESD.

The iTask editor for Digraph values performs the following actions for a \( d :: \text{Digraph String} \) identified by name. First, compute \( e = \text{toString} \) and save \( e \) in file name.dot. Second, invoke \( dot \) on \( name.dot \), which yields a rendering as name.gif. Third, invoke \( dot \) to create a name.map file to allow the user to select states. Fourth, alter the lines in name.map to invoke a script that sends the label of the selected state to the server application. Finally, generate the proper HTML to be included in the application page. The server application, when receiving the label of a selected state, updates the corresponding Digraph value to reflect the change. Now the application continues with the new Digraph value.

### VI. RELATED WORK

The mCRL2 tool set [7], [7] uses a process algebraic specification language, mCRL2 [7], to describe distributed, communicating systems. It has a functional style data language with recursive types, data constructors, functions, lambda-abstraction, and structured data. It comes with an extensive number of tools (15) for analysis purposes. Five are relevant to our work: with xsm a user can explore a linearized mCRL2 specification in a similar way as with our tool, using a GUI (the simulation tool sim has a command line interface); the user can select actions, after which the tool shows the resulting state. Besides interactively exploring the mCRL2 specification, the tool set also allows to render the complete state space: NoodleView (for 2D rendering) and FSMView (for 3D rendering). Before this is possible, the state space needs to be generated with lps2lts.
The TorX tool set [9], [7] is a model based test tool to check conformance of real suts, based on the ioco theory of testing. The specification is a Labeled Transition System (LTS), or one that is derived from a higher level specification language that converts to LTS (e.g. mCRL2 described above). The tool uses the specification to automatically determine inputs, observe outputs from the sut, and make a final verdict. In this sense, it is not useful for exploring a specification. However, once a test run has been created, the user can explore the actual trace which is depicted as a message sequence chart.

The Uppaal tool set [1], [7] can be used for both validation and verification (using model checking) of time-based systems. Validation is done by means of a graphical simulator of a time-based automaton specification. The automaton specification is basically a labeled transition system with timing constraints. Uppaal allows for simple data types, clocks, and constraints on these clocks. The user can create specifications in an intuitive, graphical way. The user can stepwise direct the system’s behavior, or generate a random trace.

The esmViz tool differs with the mCRL2 approach in that we use a single modeling formalism. Except for the 3D rendering all of the functionality of the mCRL2 tool set is available in esmViz. The TorX tool set is really a model based testing harness, and is less suited for exploration purposes. Specifications within Uppaal can be created graphically. In esmViz specifications are given as a function, out of which a graphical approximation is ‘discovered’ by the user or by the system. In our opinion this combines the best of both worlds: the succinctness of functional programming with the intuitive appeal of a graphical rendering.

VII. EXPERIENCES

In order to judge the quality of esmViz 10 master students in computer science studied some test cases with and without esmViz. These students are literate Clean programmers, have a basic understanding of model-based testing with GVst and the specifications needed (but no hands-on experience). After an introduction to esmViz and playing with an example similar to the beverage vending machine in this paper the students were asked to locate problems in two other case studies. The examples were heavily parameterized specifications of a number guessing game and a telephone number database that contains potentially over one million states. Drawing all these states makes finding the problems only harder. The errors in the specification can however all be found by traces of about ten to twenty transitions.

The students found esmViz very handy to get a feeling for the behavior of the specified system. Everybody found it much easier to understand a specified system with the tool than without. Finding errors in the specification by simulation remains hard, but the tool makes it easier. The same holds for finding the source of issues found by GVst. This is consistent with the general observation in all kinds of testing: finding issues is one thing, but finding their cause is another.

VIII. CONCLUSIONS

There are two kinds of conclusions from the work described in this paper. First, the specification simulator esmViz described in this paper really helps a lot to understand the behavior of the extended state machines used as specification in model-based testing. Although the compiler of the statically typed functional programming language used as carrier of these specifications checks the models, the models can still contain errors. Finding these semantics errors is hard. The simulator helps in locating these problems, especially if an appropriate constraint on transitions or states is known. Second, implementing such a tool with iTasks is a real pleasure. Integrating Graphviz with iTasks turned out to be smooth. Implementing a browser interface for esmViz using the iTask system imposes some restrictions on the layout of the GUI, but works well. The different possible user actions are modeled each by an iTask. The iTask system is well suited to compose these tasks in a flexible way and takes care of rendering them.
