Golgi antiapoptotic protein (GAAP) is a novel regulator of cell death that is highly conserved in eukaryotes and present in some poxviruses, but its molecular mechanism is unknown. Given that alterations in intracellular Ca\(^{2+}\) homeostasis play an important role in determining cell sensitivity to apoptosis, we investigated if GAAP affected Ca\(^{2+}\) signaling. Overexpression of human (h)-GAAP suppressed staurosporine-induced, capacitative Ca\(^{2+}\) influx from the extracellular space. In addition, it reduced histamine-induced Ca\(^{2+}\) release from intracellular stores through inositol trisphosphate receptors. h-GAAP not only decreased the magnitude of the histamine-induced Ca\(^{2+}\) fluxes from stores to cytosol and mitochondrial matrices, but it also reduced the induction and frequency of oscillatory changes in cytosolic Ca\(^{2+}\). Overexpression of h-GAAP lowered the Ca\(^{2+}\) content of the intracellular stores and decreased the efficacy of IP\(_3\), providing possible explanations for the observed results. Opposite effects were obtained when h-GAAP was knocked down by siRNA. Thus, our data demonstrate that h-GAAP modulates intracellular Ca\(^{2+}\) fluxes induced by both physiological and apoptotic stimuli.

INTRODUCTION

Recently, a novel regulator of cell death was identified (Gubser et al., 2007). This protein was named Golgi antiapoptotic protein (GAAP) because of its predominant localization in the Golgi and its ability to suppress apoptosis. GAAP is a predicted seven-transmembrane protein and was identified initially in certain poxviruses (vaccinia virus and camelpox virus) where it affects virus virulence. GAAPs are highly conserved in a broad range of organisms including human, orangutan, dog, mouse, rat, *Xenopus laevis*, and zebrafish, and related proteins are present in *Drosophila* and *Arabidopsis*. Human (h)-GAAP is expressed ubiquitously in human tissue and shares 73% aa identity with viral (v)-GAAP. Stable expression of either v-GAAP or h-GAAP suppressed cell death induced by a broad variety of intrinsic and extrinsic apoptotic stimuli. Conversely, knockdown of h-GAAP in tissue culture cells by siRNA resulted in cell death.

Ca\(^{2+}\) functions as a ubiquitous intracellular signal to many different biological processes. Ca\(^{2+}\)-induced signaling arises from Ca\(^{2+}\) entry across the plasma membrane and/or release from intracellular stores, predominantly the endoplasmic reticulum (ER) and Golgi. Ca\(^{2+}\) is released from intracellular stores by inositol-1,4,5-trisphosphate (IP\(_3\)), which interacts with IP\(_3\) receptors (IP\(_3\)R) that are Ca\(^{2+}\)-release channels present in the ER and Golgi (Pinton et al., 1998). Furthermore, IP\(_3\)R activity is modulated by Ca\(^{2+}\) itself, ATP, phosphorylation, and interacting proteins (Foskett et al., 2007). Ca\(^{2+}\) that enters the cytosol activates cytosolic enzymes and is taken up by mitochondria, which play an important role in decoding Ca\(^{2+}\) signals during normal cell physiology (Berridge et al., 2003). Mitochondrial Ca\(^{2+}\) uptake is mediated by a low-affinity Ca\(^{2+}\) uniporter that senses the high Ca\(^{2+}\) microdomains that are established at the tight junctions between the ER and mitochondria (Rizzuto et al., 1998). Recently, tight junctions with a putative role in Ca\(^{2+}\) signaling were also observed between Golgi and mitochondria (Dolman et al., 2005).

Alterations in the finely tuned intracellular Ca\(^{2+}\) homeostasis and compartmentalization contribute to the induction of apoptosis. The switch from the control of physiological functions to the involvement in this death program most likely entails changes in the tightly regulated spatiotemporal Ca\(^{2+}\) signaling pattern affecting cytosolic effector proteins and effector organelles (Orrenius et al., 2003). Ca\(^{2+}\)
signaling between storage organelles and mitochondria plays an important role in sensitizing cells to apoptosis (Pinton and Rizzuto, 2006). Molecular and pharmacological approaches that lowered Ca2+ levels in the stores and thereby reduced Ca2+ signaling to the mitochondria, protected cells from apoptosis, whereas conditions that increased Ca2+ levels in the stores had the opposite effect (Ma et al., 1999; Nakamura et al., 2000; Pinton et al., 2001; Pinton and Rizzuto, 2006). Moreover, both antiapoptotic (e.g., Bcl-2 and Bcl-xL) and proapoptotic (e.g., Bak and Bak) partially localize at the ER to regulate Ca2+ signaling (Oakes et al., 2003; Chen et al., 2004; White et al., 2005).

On the basis of the localization of h-GAAP at intracellular Ca2+ stores and the established importance of intracellular Ca2+ signaling in sensitizing cells to apoptosis induction, we hypothesized that the antiapoptotic role of h-GAAP may be mediated by modulating the Ca2+ content of these stores and/or the flux of Ca2+ between these stores and the closely opposed mitochondria. Here, evidence is presented that h-GAAP alters intracellular Ca2+ fluxes induced by both a physiological stimulus (histamine) and an apoptotic stimulus (staurosporine).

**MATERIALS AND METHODS**

**Cells and Medium**

U2OS-neo and U2OS-h-GAAP cell lines were described previously (Gubser et al., 2007). Cells were grown in minimal essential medium (Invitrogen, Carlsbad, CA) supplemented with 10% (vol/vol) fetal bovine serum and 10 µg/ml Ciproxin (Bayer, Newbury, Berks, United Kingdom) at 37°C in a 5% CO2 atmosphere.

**Antibodies, Conjugates, and Reagents**

Mouse monoclonal antibodies against IP3R3, calnexin, Bcl-2, and paxillin were obtained from BD Transduction Laboratories (Lexington, KY); Mouse mAb against protein disulfide isomerase (PDI) was from StressGen (San Diego, CA), against Bcl-XL from Santa Cruz Biotechnology (Santa Cruz, CA) and against h-GAAP from Upstate Laboratories (Lake Placid, NY). Rabbit polyclonal antibodies against Bax and Bak were from Cell Signaling Technology (Beverly, MA). Rabbit polyclonal antibody (Rbt 476) against IP3R (all isoforms) was described previously (Ma et al., 2002). Coelenterazine-W, coelenterazine-N, fura-2 acetoxymethyl ester (fura-2/AM), and Rhod-2/AM were from Molecular Probes (Eugene, OR). histamine and ionomycin from elenterazine-N, fura-2 acetoxymethyl ester (fura-2/AM), and Rhod-2/AM Ca2+ excited at 380 and 540 nm, respectively. The fura-2 fluorescence emission is described for Bcl-2 interaction with 1 ml of 2% SDS for 30 min. For each data point, the amount of radioactivity that was still present in the stores was calculated, expressed as a percentage of the total amount present at the onset of the experiment, and plotted as a function of time.

**Calculations**

Data are presented as mean values ± SEM. Differences were tested for significance using the Student’s t-test.

**RESULTS**

**h-GAAP Decreases Cytosolic and Mitochondrial Ca2+ Rises Triggered by an Apoptotic Stimulus**

In this study, possible effects of h-GAAP on intracellular Ca2+ signaling were investigated using U2OS cells that stably expressed hemagglutinin (HA)-tagged h-GAAP predominantly at the Golgi but also at the ER (hereafter referred to as h-GAAP cells; Gubser et al., 2007). Essentially the same results were obtained with two independently constructed h-GAAP cell lines. Except in experiments in which parental U2OS cells were transfected with siRNA, U2OS cells containing the empty plasmid vector were used as a control (hereafter referred to as U2OS-neo cells). Western blot analysis was performed to exclude the possibility that h-GAAP overexpression affected the expression levels of ER chaperones or Bcl-2 family members. The data show that the expression levels of calnexin, PDI, Bcl-2, Bcl-xL, Bax, and Bak in h-GAAP cells was not altered compared with U2OS-neo cells (Supplementary Figure S1).

Previously, staurosporine (STS)-induced apoptosis was demonstrated to be partially, but significantly, inhibited in h-GAAP cells (Gubser et al., 2007). The exact mechanism by which STS induces cell death is unknown, but STS-induced cell death is at least partially Ca2+-dependent (Oakes et al., 2003; Chen et al., 2004; White et al., 2005). Therefore, we first addressed a possible role of h-GAAP in the STS-induced changes in intracellular Ca2+ homeostasis (Boehning et al., 2003; Chen et al., 2003). To this end, cells were loaded with the cytosolic Ca2+ indicator fura-2 and the mitochondrial Ca2+ indicator Rhod-2, treated with STS, and analyzed by digital imaging microscopy. Initial measurements of the resting cytosolic Ca2+ concentration using fura-2 revealed no detectable differences between U2OS-neo and h-GAAP cells (resting fura-2 ratio in U2OS-neo cells was 0.35 ± 0.02, n = 85 cells, measured on 5 d; resting fura-2 ratio in h-GAAP was 0.35 ± 0.01, n = 85 cells, measured on 5 d). On addition of 2 µM STS, U2OS-neo cells displayed a gradual increase in both mitochondrial and cytosolic Ca2+ concentration (Figure 1, A and B). Both increases were virtually abolished by 2-aminooxy-diphenylborate (2-APB), a drug that suppresses extracellular Ca2+ entry by inhibiting store-operated Ca2+ channels and indicating that STS acts to stimulate the capac-
and GAAP cells transfected with mitochondrion-targeted aequorin. \* p < 0.05. (E) IP₃R expression levels in neo and h-GAAP cells lysates were determined by immunoblotting using an antibody recognizing all three IP₃R isoforms. Proteins were resolved by using 4–15% linear gradient SDS-PAGE.

**h-GAAP Coimmunoprecipitates with the IP₃R**

The above results suggested that h-GAAP might interact with IP₃Rs thus providing a potential explanation for its inhibitory effect on the flux of Ca²⁺ through these receptors. Because currently there exists no good antibody against h-GAAP for immunoprecipitation purposes, we made use of...
the HA-tag that was fused to h-GAAP. The results obtained show that the anti-HA mAb coprecipitated IP3R subtype 3 (IP3R3; Figure 2A), which is the most abundant subtype in U2OS cells (data not shown). The specificity of this reaction was confirmed by the failure of the antibody to precipitate any sarcoendoplasmic reticulum Ca2+/H1001-ATPase isoenzyme 2b (SERCA2b), the predominant SERCA protein in non-muscle cells. In the reciprocal experiment, immunoprecipitation of IP3R3 brought down h-GAAP (Figure 2B). These results demonstrate that h-GAAP interacts, either directly or indirectly, with the IP3R.

**h-GAAP Lowers the Amount of Stored Ca2+ in Intact Cells**

Because h-GAAP can be coprecipitated with IP3R, we next assessed the possibility that it might affect the characteristics of the IP3-induced Ca2+ release response. To gain access to the IP3R, we made use of a permeabilized cell system. Cells were permeabilized with saponin, loaded to steady state with 45Ca2+, washed to remove excess ATP using an efflux medium containing the SERCA inhibitor TG to prevent Ca2+-reuptake, and challenged with either the Ca2+ ionophore A23187, to determine total releasable 45Ca2+ or the indicated concentration of IP3. After 2 min, the time required for completion of the rapid phase of the IP3-induced Ca2+ release response, the medium was removed, and the amount of 45Ca2+ released was determined, corrected for passive 45Ca2+ leakage, and expressed as percentage of total releasable 45Ca2+. Maximum stimulation with IP3 released a significantly smaller fraction of total releasable Ca2+ in h-GAAP cells (p < 0.005, Figure 2C). The latter finding was not likely to be due to a decrease in the number of IP3Rs because immunoblot analysis of cell lysates revealed no detectable difference in expression of the most abundant subtype 3 (Figure 2A).

Calculation of the EC50 value showed that h-GAAP did not affect the sensitivity for IP3 (1.35 ± 0.33 and 1.28 ± 0.14 μM IP3 for U2OS-neo and h-GAAP cells, respectively). We observed a small effect of h-GAAP on the cooperativity of the IP3-induced Ca2+ release response, as measured by calculation of the Hill coefficient (1.22 ± 0.22 and 1.02 ± 0.15 for U2OS-neo and h-GAAP cells, respectively), but this difference was not statistically significant. These results indicate that h-GAAP decreases the efficacy of IP3 without altering its potency. It remains to be established whether this involves a direct or indirect interaction between h-GAAP and IP3R.

**h-GAAP Alters Cellular Calcium Handling**

Because h-GAAP can be coprecipitated with IP3R, we next assessed the possibility that it might affect the characteristics of the IP3-induced Ca2+ release response. To gain access to the IP3R, we made use of a permeabilized cell system. Cells were permeabilized with saponin, loaded to steady state with 45Ca2+, washed to remove excess ATP using an efflux medium containing the SERCA inhibitor TG to prevent Ca2+-reuptake, and challenged with either the Ca2+ ionophore A23187, to determine total releasable 45Ca2+ or the indicated concentration of IP3. After 2 min, the time required for completion of the rapid phase of the IP3-induced Ca2+ release response, the medium was removed, and the amount of 45Ca2+ released was determined, corrected for passive 45Ca2+ leakage, and expressed as percentage of total releasable 45Ca2+. Maximum stimulation with IP3 released a significantly smaller fraction of total releasable Ca2+ in h-GAAP cells (p < 0.005, Figure 2C). The latter finding was not likely to be due to a decrease in the number of IP3Rs because immunoblot analysis of cell lysates revealed no detectable difference in expression of the most abundant subtype 3 (Figure 2A).

Calculation of the EC50 value showed that h-GAAP did not affect the sensitivity for IP3 (1.35 ± 0.33 and 1.28 ± 0.14 μM IP3 for U2OS-neo and h-GAAP cells, respectively). We observed a small effect of h-GAAP on the cooperativity of the IP3-induced Ca2+ release response, as measured by calculation of the Hill coefficient (1.22 ± 0.22 and 1.02 ± 0.15 for U2OS-neo and h-GAAP cells, respectively), but this difference was not statistically significant. These results indicate that h-GAAP decreases the efficacy of IP3 without altering its potency. It remains to be established whether this involves a direct or indirect interaction between h-GAAP and IP3R.
tion will lead to passive release of stored Ca\(^{2+}\) into the cytosol. The results show that both BHQ (Figure 3A) and ionomycin (Figure 3B) evoked a transient rise in cytosolic Ca\(^{2+}\) concentration, the amplitude of which was significantly reduced in h-GAAP cells. Importantly, and in contrast to what was observed with histamine, the upstroke of the Ca\(^{2+}\) transients induced by BHQ and ionomycin was unaltered in h-GAAP cells.

To investigate the effects of h-GAAP on the Ca\(^{2+}\) concentration in ER and Golgi separately, cells were transfected with organelle-targeted aequorins, permeabilized with saponin at 20 h after transfection, and assayed for ATP-dependent Ca\(^{2+}\) uptake under “cytosolic" conditions at a free Ca\(^{2+}\) concentration of 0.1 μM. In both organelles the steady-state Ca\(^{2+}\) concentration appeared lower (~20%) in h-GAAP cells (p < 0.01, Figure 3C and D). Importantly, no major differences in the initial rate of Ca\(^{2+}\) uptake were observed, indicating that h-GAAP does not alter the SERCA pump capacity of the intracellular stores.

To establish more firmly that h-GAAP has an effect on the steady-state Ca\(^{2+}\) content of the intracellular stores, we next determined this content at different times after transfection of parental U2OS cells with h-GAAP siRNA. Comparison with parental U2OS cells transfected with control siRNA revealed no detectable difference at 20 h after transfection (Figure 3E). At 40 h after transfection, however, the amplitude of the ionomycin-induced increase in cytosolic Ca\(^{2+}\) concentration was significantly higher (~35%) in h-GAAP down-regulated cells (p < 0.001). Organelle-targeted aequorins revealed that this increase in Ca\(^{2+}\) concentration occurred in both ER and Golgi (p < 0.05, Figure 3F).

**hGAAP Decreases the Sensitivity to Histamine Induction of Oscillatory Cytosolic Ca\(^{2+}\) Changes**

In the experiments described thus far, cells were stimulated with a “pharmacological” concentration of histamine (100 μM). In the remainder of this study, we assessed the possible consequences of these findings on Ca\(^{2+}\) signaling in intact cells under more “physiological” conditions. Cells were loaded with fura-2 and superfused with medium containing (sub)micromolar concentrations of histamine. Digital imaging microscopy of individual cells revealed that 0.3 and 1.0 μM histamine increased the cytosolic Ca\(^{2+}\) concentration in ~70 and ~95% of the U2OS-neo cells, respectively. For h-GAAP cells, these values were ~20 and ~70%, respectively, indicating a reduced sensitivity to hormonal induction of an increase in cytosolic Ca\(^{2+}\) concentration. In a small percentage of the responding U2OS-neo cells (~5–10% at 1.0 μM histamine), the initial large Ca\(^{2+}\) transient was followed by Ca\(^{2+}\) oscillations (Figure 4, A and B). These Ca\(^{2+}\) oscil-
DISCUSSION

In this study, evidence is presented that h-GAAP, a novel regulator of cell death, reduces both extracellular Ca^{2+} influx evoked by staurosporine, a widely used apoptosis inducer, and intracellular Ca^{2+} release evoked by histamine, known to exert its effect on intracellular Ca^{2+} through IP_3.

Using a permeabilized cell system, which allows experimental control of the cytosolic compartment, h-GAAP overexpression was demonstrated to lower the efficacy of IP_3, as demonstrated by a reduction of the maximum amount of total (A23187-) releasable Ca^{2+} that could be released by IP_3. Because neither the amount of IP_3Rs nor their affinity for IP_3 were detectably altered in h-GAAP-overexpressing cells, this result suggests that h-GAAP either decreases IP_3-sensitive part of the (A23187)- releasable Ca^{2+} store or, alternatively, decreases the Ca^{2+} release properties of the IP_3-channels. In intact cells, h-GAAP overexpression was shown to reduce the amount of total (ionomycin- or BHQ-) releasable Ca^{2+}, consistent with a reduced filling state of the intracellular stores. Consistent with the above results, the cytosolic and mitochondrial Ca^{2+} increases in response to a pharmacological histamine concentration (100 μM) were down-regulated in intact cells overexpressing h-GAAP and up-regulated when h-GAAP was knocked down. Furthermore, stimulation with a more close to physiological concentration of histamine (1 μM) revealed that h-GAAP rendered cells less sensitive to the induction of cytosolic Ca^{2+} oscillations, characteristic for these low concentrations of histamine. Together, these data suggest that h-GAAP reduces both the total amount of releasable Ca^{2+} and its maximum amount that can be released by IP_3, thereby attenuating IP_3-induced cytosolic and mitochondrial Ca^{2+} signaling.

How h-GAAP exerts these effects remains to be established. In this study, we showed that h-GAAP inhibits the influx of extracellular Ca^{2+} influx and decreases the IP_3-mediated release of Ca^{2+} from the stores. In addition, we showed that h-GAAP coprecipitated with IP_3Rs, suggesting an interaction. Such an interaction, which may be either direct or indirect, could be involved in the ability of h-GAAP...
to suppress Ca$^{2+}$ fluxes. However, the observed effects of h-GAAP may equally well be explained by its ability to reduce the filling state of the Ca$^{2+}$ stores. Therefore, the importance of this interaction for the observed function of h-GAAP requires further investigation.

A reduction in Ca$^{2+}$ filling state of the intracellular stores is usually associated with an increase in capacitative Ca$^{2+}$ entry across the plasma membrane, resulting in an increase in cytosolic Ca$^{2+}$ concentration. However, under resting conditions no such increase in cytosolic Ca$^{2+}$ concentration was observed in cells overexpressing h-GAAP, despite a decrease in the amount of total releasable Ca$^{2+}$. This result suggests that h-GAAP exerts an inhibitory effect on the process of capacitative Ca$^{2+}$ entry. In agreement with this idea, the STS-induced increase in cytosolic and mitochondrial Ca$^{2+}$ concentration, which depended completely on the presence of extracellular Ca$^{2+}$ and was abolished by 2-APB, an inhibitor of capacitative Ca$^{2+}$ entry channels, was decreased in cells overexpressing h-GAAP and was increased in cells in which this protein was down-regulated. STS and histamine increased the cytosolic Ca$^{2+}$ concentration with different kinetics, a relatively slow increase after addition of STS versus a relatively fast increase after stimulation with different kinetics, a relatively slow increase after stimulation with histamine under steady-state conditions (White et al., 2003). Regulation of endoplasmic reticulum Ca$^{2+}$ concentration by 2-aminoethoxydiphenyl borate in DT40 lymphocytes. J. Biol. Chem. 278, 17545–17550.
