Abstract

In this paper, we describe a symbolic synthesis method which given an algebraic expression that specifies a bitstream function $f$, constructs a (minimal) Mealy machine that realises $f$. The synthesis algorithm can be seen as an analogue of Brzozowski’s construction of a finite deterministic automaton from a regular expression. It is based on a coinductive characterisation of the operators of 2-adic arithmetic in terms of stream differential equations.

1 Introduction

A (binary) Mealy machine is a deterministic automaton which in each step reads an input bit, produces an output bit and moves to a next state. The induced mapping of input streams to output streams is a causal bitstream function, which we call the bitstream function realised by the Mealy machine. In this paper, we describe a symbolic synthesis method which given an algebraic expression that specifies a bitstream function $f$, constructs a minimal Mealy machine that realises $f$.

The inputs to our synthesis algorithm are called function expressions and they define bitstream functions in the algebra of 2-adic numbers. Here we use that the formal power series representation of a 2-adic integer can be seen as the bitstream of its coefficients. We describe the 2-adic algebra below, but for now such a function expression can be thought of as a specification of a function on the rational numbers. The interesting property of 2-adic arithmetic is that it allows us to calculate with bitstream representations of rational numbers in an easy manner similar to how one computes with integers.

The synthesis algorithm described here can be seen as an analogue of Brzozowski’s construction in [3] of a finite deterministic automaton from a regular expression. In particular, we show that the set of function expressions carries the structure of a Mealy machine by giving an inductive
definition of derivative and output of function expressions. This Mealy ma-
chine of expressions is defined in such a way that the algebraic semantics
coincides with the behavioural semantics of Mealy machines, which will be
defined in terms of causal stream functions. Now given a function expression
F specifying a function f, we obtain a realisation of f by the symbolic compu-
tation of the (sub)machine generated by F. (The generated submachine is in
general not minimal, but we can ensure minimality by reducing expressions
to normal form.) The language of 2-adic arithmetic allows the specification
of functions that cannot be realised by any finite Mealy machine. But we
shall identify a subclass of so-called rational function expressions for which
a finite realisation exists.

In the design of digital hardware, Mealy machines specify the behaviour
of sequential circuits, and there exist algorithms which construct from a
(finite) Mealy machine, a sequential circuit which exhibits the specified be-
haviour. Combining these algorithms with our synthesis algorithm we thus
obtain a complete construction from algebraic specification to sequential
circuit.

In summary, the main contributions of the present paper are: (1) The
elementary but useful observation that the set of all causal stream functions
constitutes a final Mealy machine, which forms the basis for a behavioural
semantics of Mealy machines in terms of their minimisation. (Although
minimisation of Mealy automata is well known [4], its characterisation here
by means of finality is new.) (2) The insight that given a rational func-
tion expression F, we can effectively construct by symbolic computation a
(minimal) Mealy machine that realises the bitstream function specified by F.

The basis for the present synthesis algorithm was given in [17]. These
ideas were developed into a proper algorithm in [8] (for an implementa-
tion, see [7]). Further results on complexity and size of realisations were
included in the first author’s PhD thesis [6, Ch. 3]. This paper contains a
short, but improved presentation of the basic results in the abovementioned
work. In particular, the presentation of the Mealy machine of expressions,
the algebraic semantics of function expressions, and the proof that algebraic
semantics coincides with behavioural semantics for function expressions are
new with respect to [6, 8, 17]. Finally, we mention that the theory un-
derlying the present work is essentially coalgebraic (cf. [14]), but we have
deliberately chosen for a presentation which does not require any familiarity
with coalgebra.

Structure of the paper: In Section 2 we give the basic definitions re-
arding Mealy machines. In Section 3 we describe the 2-adic algebra of
bitstreams and define the function expressions which serve as our specifica-
tion language. In Section 4 we show how function expressions can be turned
into a Mealy machine, and Section 5 describes the synthesis method for
rational functions. Finally, we discuss related and future work in Section 6.
2 Mealy Machines

We give the basic definitions on Mealy machines, streams and causal stream functions. We introduce the notion of stream function derivative and show how it can be used to turn the set of causal stream functions into a final Mealy machine, thus providing a characterisation of minimal Mealy machines.

Let $A$ and $B$ be arbitrary sets. A Mealy machine $\langle S, m \rangle$ with inputs in $A$ and outputs in $B$ consists of a set of states $S$ and a transition function

$$m: S \to (B \times S)^A$$

This function maps a state $s_0 \in S$ to a function $m(s_0): A \to (B \times S)$, which produces for every input $a \in A$ a pair $(b, s_1)$, consisting of the output $b$ and the next state $s_1$. We call a Mealy machine binary if inputs and outputs are taken from the set $2 = \{0, 1\}$. We will write $s_a \mid b \to t$ iff $m(s_0)(a) = (b, t)$.

For an arbitrary set $A$, we denote by $A^\omega$ the set of streams over $A$, i.e., $A^\omega = \{\alpha \mid \alpha: \mathbb{N} \to A\}$. An element $\alpha \in A^\omega$ will be denoted by $\alpha = (\alpha(0), \alpha(1), \alpha(2), \ldots)$. The head and tail maps on streams are denoted by $hd$ and $tl$, respectively, that is, for $\alpha \in A^\omega$, $hd(\alpha) = \alpha(0)$ and $tl(\alpha) = (\alpha(2), \alpha(3), \ldots)$. Later, in the context of stream differential equations, we will also refer to $hd(\alpha)$ and $tl(\alpha)$ as the initial value and stream derivative of $\alpha$, respectively, and write $\alpha'$ instead of $tl(\alpha)$. Moreover, for $\alpha \in A^\omega$ and $n \in \mathbb{N}$, we write $\alpha \restriction_n$ for the finite prefix $(\alpha(0), \ldots, \alpha(n))$.

We define the (input-output) behaviour of a state $s_0$ in $S = \langle S, m \rangle$ as the stream function $beh_S(s_0): A^\omega \to B^\omega$ which maps an input stream $(a_0, a_1, a_2, \ldots) \in A^\omega$ to the output stream $(b_0, b_1, b_2, \ldots) \in B^\omega$ given by the unique sequence of transitions

$$s_0 \xrightarrow{a_0} d_{b_0} \quad s_1 \xrightarrow{a_1} d_{b_1} \quad \ldots \quad s_k \xrightarrow{a_k} d_{b_k} \quad s_{k+1} \xrightarrow{a_{k+1}} d_{b_{k+1}} \quad \ldots$$

If $S$ is clear from the context, we will often leave out the subscript and simply write $beh(s)$. We say that a state $s$ in $\langle S, m \rangle$ realises a stream function $f$ if $beh(s) = f$.

Example 2.1 The figure below shows an example of a binary Mealy machine which starting in state $s_0$ counts the number of ones in the input modulo 2. Formally, $s_0$ realises the function $f$ defined on input streams $\alpha \in 2^\omega$ by $f(\alpha)(n) = \sum_{i=0}^n \alpha(i) \mod 2$ for all $n \in \mathbb{N}$.
Note that, for any $\alpha \in 2^\omega$ and $n \in \mathbb{N}$, $f(\alpha)(n)$ is determined by $\alpha(0), \ldots, \alpha(n)$.

We call a stream function $f : A^\omega \to B^\omega$ causal if the $n$-th element of the output stream $f(\alpha)$ depends only on the first $n$ elements of the input stream. More formally, $f$ is causal if for all $n \geq 0$ and all $\alpha, \beta \in A^\omega$:

$$\alpha|_n = \beta|_n \implies f(\alpha)(n) = f(\beta)(n).$$

It is straightforward to prove that for any Mealy machine $\langle S, m \rangle$ and any $s \in S$, $beh(s) : A^\omega \to B^\omega$ is causal. Let $\Gamma$ denote the set of all causal stream functions, i.e.,

$$\Gamma = \{ f \mid f : A^\omega \to B^\omega \text{ and } f \text{ is causal} \}.$$

We now show that $\Gamma$ itself can be turned into a Mealy machine. For $\alpha \in A^\omega$ and $a \in A$, we denote by $a : \alpha$ the stream $(a, \alpha(0), \alpha(1), \alpha(2), \ldots)$, and given $f : A^\omega \to B^\omega$, we write $f(a : -)$ for the stream function that maps $\alpha$ to $f(a : \alpha)$. Now let $f \in \Gamma$ and $a \in 2$. We define

$$f[a] := h_d \circ f(a : -) \in A^\omega \to B$$

$$f_a := t_l \circ f(a : -) \in A^\omega \to B^\omega$$

Since $f$ is causal, it follows that also $f_a$ is causal (hence $f_a \in \Gamma$), and that $f[a]$ is constant, hence $f[a]$ can be considered an element of $B$. We call $f[a]$ the initial output of $f$ on input $a$, and $f_a$ is the stream function derivative of $f$ on input $a$. We define the transition function

$$\gamma : \Gamma \to (B \times \Gamma)^A \quad \text{by} \quad \gamma(f)(a) = \langle f[a], f_a \rangle \text{ for all } f \in \Gamma, a \in A.$$

This gives us an (infinite) Mealy machine $\Gamma = \langle \Gamma, \gamma \rangle$ with transitions

$$f \xrightarrow{a[f[a]]} f_a$$

Next we characterise $\langle \Gamma, \gamma \rangle$ using the following notion. A homomorphism of Mealy machines from $\langle S, m \rangle$ to $\langle S', m' \rangle$ is a function $h : S \to S'$ that preserves transitions: if $m(s)(a) = \langle b, t \rangle$ then $m'(h(s))(a) = \langle b, h(t) \rangle$; in other words,

$$s \xrightarrow{a|b} t \quad \Rightarrow \quad h(s) \xrightarrow{a|b} h(t)$$

**Theorem 2.2** For any Mealy machine $S = \langle S, m \rangle$, the behaviour map $beh_S : S \to \Gamma$ is the unique homomorphism from $S$ to $\Gamma$. In other words, $\Gamma$ is a final Mealy machine.

**Proof.** Let $\langle S, m \rangle$ be an arbitrary Mealy machine. We denote the output and next state functions defined by $m$ at state $s \in S$ by $o_s$ and $d_s$,
respectively, that is, \( m(s)(a) = \langle o_s(a), d_s(a) \rangle \). To see that \( \text{beh}: S \rightarrow \Gamma \) is a homomorphism, let \( s \in S \), \( a \in A \) and \( \alpha \in A^\omega \) be arbitrary. We have:

\[
\text{beh}(s)[a] = \text{hd}(\text{beh}(s)(a: \alpha)) = o_s(a),
\]

and by letting \( s_0 = d_s(a) \) and \( s_{i+1} = d_{s_i}(\alpha(i)) \) for all \( i \geq 0 \), we have

\[
(\text{beh}(s)_a)(\alpha) = \text{tl}(\text{beh}(s)(a: \alpha)) = \text{tl}(o_s(a), o_{s_0}(\alpha(0)), o_{s_1}(\alpha(1)), \ldots) = (o_{s_0}(\alpha(0)), o_{s_1}(\alpha(1)), \ldots) = \text{beh}(d_s(a))(\alpha).
\]

Hence \( \text{beh}(s)_a = \text{beh}(d_s(a)) \). The proof that \( \text{beh}: S \rightarrow \Gamma \) is the unique homomorphism from \( S \) to \( \Gamma \) is left to the reader. \( \text{QED} \)

The universality of \( (\Gamma, \gamma) \) can be expressed in yet another way. We need the following notions. For a state \( s \in S \) of a Mealy machine \( \langle S, m \rangle \), let

\[
\langle s \rangle \subseteq S
\]

denote the smallest subset that contains \( s \) and is closed under transitions (for any inputs). Clearly, \( \langle s \rangle \) is also a submachine of \( \langle S, m \rangle \), by taking as its transition function the restriction of \( m \) to the set \( \langle s \rangle \). We call \( \langle s \rangle \) the submachine generated by \( s \) in \( \langle S, m \rangle \). We call \( \langle s \rangle \) a realisation of \( f \), if \( \text{beh}_S(s) = f \), i.e., \( s \) realises \( f \) (in \( S \)). We say that a Mealy machine \( \langle S, m \rangle \) is minimal if \( \text{beh}: \langle S, m \rangle \rightarrow (\Gamma, \gamma) \) is injective. From the finality of \( \Gamma \), we get:

**Corollary 2.3** For all \( f \in \Gamma \), \( \langle f \rangle \) is a minimal realisation of \( f \).

**Proof.** Follows from the fact that the inclusion map \( \langle f \rangle \rightarrow \Gamma \) is an injective homomorphism of Mealy machines. \( \text{QED} \)

The final Mealy machine \( \Gamma \) thus consists of all the behaviours that can be realised by some Mealy machine, and we therefore refer to \( \text{beh}(s) \) as the behavioural semantics of a state \( s \).

For a causal stream function \( f: A^\omega \rightarrow B^\omega \), we use the following notation for repeated stream function derivatives: for \( w \in A^* \) and \( a \in A \), we define \( f_w = f \) (where \( \varepsilon \) is the empty word) and \( f_{wa} = (f_w)_a \). Hence the state set of \( \langle f \rangle \) equals the set \( \{ f_w \ | \ w \in A^* \} \) of all stream function derivatives of \( f \).

**Example 2.4** We illustrate the notions and results above with the binary counter from Example 2.1. Let \( f = \text{beh}(s_0) \), \( g = \text{beh}(s_1) \) and \( h = \text{beh}(s_2) \). It can easily be seen that \( f = h \) and \( g(\alpha)(k) = 1 \) for all \( \alpha \in 2^\omega \) and \( k \in \mathbb{N} \). Moreover, we have the following initial outputs and stream function derivatives:

\[
\begin{align*}
f[0] &= 0, & f[1] &= 1, & g[0] &= 1, & g[1] &= 0, & f_0 &= f, & f_1 &= g, & g_0 &= g, & g_1 &= f \\
\end{align*}
\]
and thus \( \text{beh} \) maps \( S = \langle s_0 \rangle \) to its minimisation \( \langle f \rangle \subseteq \Gamma \), on the right:

\[
\begin{array}{c}
0 \downarrow 0 & 0 \downarrow 1 & 1 \downarrow 0 & 0 \downarrow 0 \\
\bigcirc s_0 & \bigcirc s_1 & \bigcirc s_2 & f \\
1 \uparrow 1 & 1 \uparrow 1 & 1 \uparrow 1 & 0 \downarrow 1
\end{array}
\]

In algebra, the behaviour of Mealy machines is typically described in terms of functions of type \( A^+ \rightarrow B \). Although this set is isomorphic to \( \Gamma \), we prefer to work with the latter because of the rich algebraic structure on streams. The notion of stream function derivative already occurs in [12], and is called \textit{state} there. It is also a variation on the classical notion of derivative (or inverse) of functions from \( A^* \) to \( B^* \) (cf. [4]). Also Theorem 2.2 and Corollary 2.3 are essentially reformulations of classical results.

The main contribution of the present paper consists of the observation that \( \langle f \rangle \) can often be constructed by a symbolic computation of stream function derivatives starting from an algebraic specification of \( f \). In Section 5, we shall describe such a symbolic algorithm for bitstream functions specified in 2-adic arithmetic.

### 3 The 2-Adic Bitstream Algebra

We will specify bitstream functions in the algebra of 2-adic integers (cf. [5]). A 2-adic integer is usually written as a (formal) power series of the form \( \sum_{i=0}^{\infty} a_i 2^i \) where \( a_i \in 2 \) for all \( i \in \{0, 1, 2, \ldots\} \). We identify such a power series with the bitstream \((a_0, a_1, a_2, \ldots)\), so for us the set of 2-adic integers is simply the set \( 2^\omega \) of bitstreams.

There is a (strict) inclusion of the set of rational numbers with odd denominator

\( \mathbb{Q}_{\text{odd}} = \{ p/q \mid p, q \in \mathbb{Z}, q \text{ odd} \} \)

into the 2-adic integers by taking infinitary base 2 expansions (see e.g. [9]). For a positive integer \( n \), this is just the binary representation of \( n \) (least significant bit on the left) padded with a tail of zeros; for instance,

\[
\begin{align*}
\text{Bin}(2) &= (0, 1, 0, 0, 0, \ldots) = 010^\omega \\
\text{Bin}(5) &= (1, 0, 1, 0, 0, \ldots) = 1010^\omega
\end{align*}
\]

Binary representations of negative integers end with an infinite sequence of ones and rational numbers (with odd denominator) have binary representations that are eventually period; for instance,

\[
\begin{align*}
\text{Bin}(-1) &= (1, 1, 1, \ldots) = 1^\omega \\
\text{Bin}(-5) &= (1, 1, 0, 1, 1, \ldots) = 1101^\omega \\
\text{Bin}(1/5) &= (1, 0, 1, 1, 0, 0, 1, 1, 0, 0, 1, 1, 0, \ldots) = 1(0110)^\omega
\end{align*}
\]
(Rationals with even denominator require formal power series representations $\sum_{i=k}^{\infty} a_i 2^i$ where $k < 0$, and are not treated here.)

Below we shall define the binary representation Bin$(q)$ of any rational $q \in \mathbb{Q}_{odd}$ by means of a stream differential equation. Such equations specify streams $\sigma$, in analogy with traditional differential calculus, in terms of their initial value $\sigma(0)$ and derivative $\sigma'$ (which are defined as $hd(\sigma)$ and $tl(\sigma)$). For instance, the differential equation

$$\sigma' = \sigma \quad \sigma(0) = 1$$

clearly defines the stream $(1, 1, 1, \ldots)$. We refer to [15] for an overview on stream differential equations.

Now let $odd(n/2m+1) = n \mod 2$ for $n, m \in \mathbb{Z}$. We define the inclusion map

$$Bin : \mathbb{Q}_{odd} \to 2^\omega$$

by the following system of stream differential equations (one for each $q \in \mathbb{Q}_{odd}$):

$$Bin(q)(0) = odd(q), \quad Bin(q)' = Bin((q - odd(q))/2)$$

(2)

The reader is invited to compute the examples of binary expansions given above, using this definition of Bin.

We recall that the set of rational numbers (with odd denominator) is an integral domain: a commutative ring in which multiplication has no zero-divisors, i.e., for all $p$ and $q$, if $p \times q = 0$ then $p = 0$ or $q = 0$. Next we shall introduce operations of addition and multiplication (as well as minus and inverse) on the set of 2-adic integers such that they reflect the operations on the rationals. More formally, we shall turn the set of 2-adic integers into an integral domain

$$\mathcal{A}_{2adic} = \langle 2^\omega, +, -, \times, /, [0], [1] \rangle$$

such that the inclusion map Bin : $\mathbb{Q}_{odd} \to 2^\omega$ is a homomorphism of integral domains.

In the literature, the operators on the 2-adic integers are often defined by explicitly specifying how they work on binary representations, see Figure 1 for examples of addition and multiplication. Their definitions are sometimes also given in terms of their representation as power series, typically in the form of some recurrence relation on their coefficients. Here we shall give, instead, a definition by means of stream differential equations, which we saw already examples of above, and which can be seen as a generalisation of definitions by recurrence, cf. [15]. Our choice to use stream differential equations is not just a matter of taste: they form the basis for the definition of the Mealy machine of stream function expressions, to be introduced in Section 4.
addition:
\[
\begin{array}{cccccc}
& 1 & 1 & 1 & \ldots \\
\hline
1 & 0 & 1 & 0 & 0 & \ldots \\
+ 0 & 1 & 1 & 1 & 1 & \ldots \\
\hline
1 & 1 & 0 & 0 & 0 & \ldots \\
\end{array}
\]
\(= 5\)  
\[
\begin{array}{cccccc}
& 1 & 1 & 0 & 0 & 0 & \ldots \\
\hline
1 & 0 & 1 & 0 & 0 & \ldots \\
+ 0 & 1 & 1 & 1 & 1 & \ldots \\
\hline
1 & 0 & 0 & 0 & 0 & \ldots \\
\end{array}
\]
\(= 3\)

multiplication:
\[
\begin{array}{cccccc}
& 1 & 1 & 0 & 0 & 0 & \ldots \\
\hline
& 0 & 0 & 0 & 0 & 0 & \ldots \\
1 & 1 & 0 & 0 & 0 & \ldots \\
1 & 1 & 0 & 0 & 0 & \ldots \\
1 & 1 & 0 & 0 & 0 & \ldots \\
\vdots \\
0 & 1 & 0 & 1 & 1 & \ldots \\
\hline
\end{array}
\]
\(= 3 \times (-2)\)

Figure 1: Examples of 2-adic addition and multiplication.

First we define the constants zero and one by
\[
[0] = (0, 0, 0, \ldots) \quad [1] = (1, 0, 0, 0, \ldots)
\]

Below we shall use the following Boolean operators on \(2 = \{0,1\}\), which are defined, for all \(a, b \in 2\), as usual: \(a \land b = \min\{a, b\}\) and \(a \oplus b = 1\) iff \(a = 0, b = 1\) or \(a = 1, b = 0\) (exclusive or).

**Definition 3.1** We define the operators of addition, minus, multiplication and inverse of 2-adic integers by the following system of stream differential equations. For \(\alpha, \beta \in 2^\omega\),

<table>
<thead>
<tr>
<th>derivative:</th>
<th>initial value:</th>
</tr>
</thead>
<tbody>
<tr>
<td>((\alpha + \beta)' = (\alpha' + \beta') + [\alpha(0) \land \beta(0)])</td>
<td>((\alpha + \beta)(0) = \alpha(0) \oplus \beta(0))</td>
</tr>
<tr>
<td>((-\alpha)' = -(\alpha' + [\alpha(0)]))</td>
<td>((-\alpha)(0) = \alpha(0))</td>
</tr>
<tr>
<td>((\alpha \times \beta)' = (\alpha' \times \beta) + ([\alpha(0)] \times \beta'))</td>
<td>((\alpha \times \beta)(0) = \alpha(0) \land \beta(0))</td>
</tr>
<tr>
<td>((1/\alpha)' = -(\alpha' \times (1/\alpha)))</td>
<td>((1/\alpha)(0) = 1)</td>
</tr>
</tbody>
</table>

There is a side condition for the definition of inverse: \(1/\alpha\) is defined only for \(\alpha\) with \(\alpha(0) = 1\).

We briefly explain the intuition behind the equations above. (For the fact that the operators above are uniquely defined by their defining stream differential equations, we refer to [15].) The equation for sum shows that a carry term must be added in case the two initial values are both 1. The equation for minus is obtained from the requirement that \((-\alpha) + \alpha = [0]\) for all \(\alpha \in 2^\omega\). By taking initial value and derivative on both sides and using the equation for +, we find that \((-\alpha)(0) \oplus \alpha(0) = 0\), hence \((-\alpha)(0) = \alpha(0)\), and
that \((-\alpha)' + \alpha' + [\alpha(0)] = [0]\), hence \((-\alpha)' = -(\alpha' + [\alpha(0)])\). The equation for the product states that for all \(\alpha, \beta \in 2^\omega\), \(\alpha \times \beta\) can be calculated using the base 2 version of shift-add-multiplication known from the multiplication in decimal notation. Finally, the multiplicative inverse of \(\alpha \in 2^\omega\) is defined only if \(\alpha(0) = 1\), since there is no bit \(a \in 2\) such that \(a \land \alpha(0) = 1\). If \(1/\alpha\) is defined then it satisfies \((1/\alpha) \times \alpha = [1]\). The equation for \(1/\alpha\) can be derived in a similar way as for \(-\alpha\).

The operations on the 2-adic numbers have been devised in such a way that \(\text{Bin}: \mathbb{Q}_\text{odd} \rightarrow A_{2\text{adic}}\) is a homomorphism of integral domains: one can easily show that, for all \(p, q \in \mathbb{Q}_\text{odd}\),

\[
\text{Bin}(p \times q) = \text{Bin}(p) \times \text{Bin}(q)
\]

(with on the left multiplication of rationals and on the right multiplication of bitstreams), and similarly for the other operators.

When calculating with the 2-adic operations it is convenient to have a constant denoting the bitstream \(\text{Bin}(2)\). We define

\[
X := \text{Bin}(2) = (0, 1, 0, 0, 0, \ldots),
\]

The constant \(X\) can be used to express some identities on bitstreams that will be useful later: For all \(\alpha \in 2^\omega\),

\[
\alpha = [\alpha(0)] + (X \times \alpha')
\]
\[\alpha + \alpha = X \times \alpha\]  \hspace{1cm} (3)

4 Mealy Machine of Expressions

We will specify bitstream functions in the language of \(A_{2\text{adic}}\) over a single variable \(s\). Formally, the set of function expressions \(\text{FExpr}\) is generated by the following grammar:

\[
\text{F, G ::= s | 0 | 1 | X | -F | F + G | F \times G | 1/(1 + (X \times F))}
\]

We use the symbols \(-, +, \times, /\) to denote the operations on bitstreams as well as the corresponding syntax constructors. The typing should always be clear from the context. We will use standard notational conventions: we write \(F^n\) for the \(n\)-fold product of \(F\) with itself, (in particular, \(F^0 = 1\) and \(F/(1 + (X \times G))\) or \(
\frac{F}{1+(X\times G)}$
\) instead of \(F \times (1/(1 + (X \times G)))\). The algebraic semantics of function expressions is given by the expected interpretation in \(A_{2\text{adic}}\). The reason we only allow division by terms of the form \(1 + (X \times F)\) is to ensure that the inverse operation is always defined when evaluating function expressions in \(A_{2\text{adic}}\).
Definition 4.1 We define the algebraic 2-adic semantics \([F]: 2^\omega \to 2^\omega\) of a function expression \(F \in \text{FExpr}\) by the following inductive clauses. Let \(\sigma\) be a bitstream,

\[
\begin{align*}
[s](\sigma) &= \sigma \\
[0](\sigma) &= [0] \\
[1](\sigma) &= [1] \\
[X](\sigma) &= X \\
[\neg F](\sigma) &= -([F](\sigma)) \\
[F + G](\sigma) &= [F](\sigma) + [G](\sigma) \\
[F \times G](\sigma) &= [F](\sigma) \times [G](\sigma) \\
[1/(1 + (X \times F)](\sigma) &= 1/(1 + (X \times [F](\sigma))
\end{align*}
\]

We say that a function expression \(F\) specifies the bitstream function \([F]\), and two function expressions \(F\) and \(G\) are equivalent (notation: \(F \equiv G\)) if \([F] = [G]\).

One easily shows (by structural induction on function expressions) that for all \(F \in \text{FExpr}\), \([F]\) is a causal bitstream function. In other words, \([\neg]\) is a map from \(\text{FExpr}\) to \(\Gamma\). We will now define a transition function \(\xi: \text{FExpr} \to (2 \times \text{FExpr})^2\) such that the algebraic semantics \([\neg] : \text{FExpr} \to \Gamma\) is a Mealy homomorphism. That is, for each \(F \in \text{FExpr}\) and \(a \in 2\), we want to define \(F[a] \in 2\) and \(F_a \in \text{FExpr}\) such that \(F[a] = [F][a]\) and \([F_a] = [F]_a\). In order to do so, first recall how we defined \(\gamma(f)(a)\) in terms of \(f(a: -), \text{hd}\) and \(tl\) (cf. equation (1)) for \(f \in \Gamma\) and \(a \in 2\). We will “mimick” \(\gamma\) in the syntax.

First, we need a syntactic version of the map \(f(a : -)\) for \(f \in \Gamma\) and \(a \in 2\). More precisely, given \(F \in \text{FExpr}\) and \(a \in 2\), we want to find a function expression which specifies \([F][a : -]\). Note that for all \(\sigma \in 2^\omega\), \([0 + (X \times s)](\sigma) = 0 : \sigma\) and \([1 + (X \times s)](\sigma) = 1 : \sigma\).

Definition 4.2 We define \(\iota: 2 \to \text{FExpr}\) by \(\iota(0) = 0\) and \(\iota(1) = 1\), and for \(F \in \text{FExpr}\) and \(a \in 2\), we let \(a : s := \iota(a) + (X \times s)\). We define \(F(a : s)\) to be the function expression obtained by uniformly substituting \(a : s\) for \(s\) in \(F\).

We now show that \(F(a : s)\) indeed specifies \([F][a : -]\).

Lemma 4.3 For all \(F \in \text{FExpr}\), all \(a \in 2\) and all \(\sigma \in 2^\omega\):

\[[F(a : s)](\sigma) = [F](a : \sigma).\]
\textbf{Proof.} The lemma is proved by a straightforward induction on the structure of $F$. We only show a few example cases:

\[
\begin{align*}
[s(a:s)](\sigma) &= [\iota(a) + (X \times s)](\sigma) \\
&= [\iota(a)](\sigma) + ([X](\sigma) \times [s](\sigma)) \\
&= [a] + (X \times \sigma) \\
\text{(cf. eqn. (3))} &= a:\sigma = [s](a:\sigma)
\end{align*}
\]

\[
\begin{align*}
[(F + G)(a:s)](\sigma) &= [F(a:s) + G(a:s)](\sigma) \\
&= [F(a:s)](\sigma) + [G(a:s)](\sigma) \\
&\underline{\text{IH}} [F](a:\sigma) + [G](a:\sigma) \\
&= [F + G](a:\sigma)
\end{align*}
\]

The transition function $\xi$ on function expressions is defined inductively over the syntactic structure. In order to motivate the definition of $\xi$, consider, for example, a product expression $F \times G$, and suppose that $[F] = f$ and $[G] = g$. We then want $[(F \times G)_a](\sigma) = tl(f(a:\sigma) \times g(a:\sigma))$ for all $\sigma \in 2^\omega$. By the stream differential equation for product, this means that

\[
[(F \times G)_a](\sigma) = (tl(f(a:\sigma)) \times g(a:\sigma)) + ([hd(f(a:\sigma))] \times tl(g(a:\sigma)))
\]

Comparing this equation with the definition of $(F \times G)_a$ below it is easy to see that an induction argument and Lemma 4.2 will show that $[(F \times G)_a] = [F \times G]_a$.

\textbf{Definition 4.4} The Mealy machine of expressions is the Mealy machine $(\text{FExpr}, \xi)$ where $\xi : \text{FExpr} \to (2 \times \text{FExpr})^2$ is given by $\xi(F)(a) = \langle F[a], F_a \rangle$ where for all $F \in \text{FExpr}$ and $a \in 2$, and $F[a]$ and $F_a$ are defined by:

\begin{center}
\begin{tabular}{|c|c|c|}
\hline
Initial output (syntax) &  & \\
\hline
$s[a] = a$ & $(-F)[a]$ & $F[a]$ \\
$0[a] = 0$ & $(F + G)[a]$ & $F[a] \oplus G[a]$ \\
$1[a] = 1$ & $(F \times G)[a]$ & $F[a] \land G[a]$ \\
$X[a] = 0$ & $(1/(1 + (X \times F)))[a] = 1$ & \\
\hline
Stream function derivative (syntax) &  & \\
\hline
$s_a = s$ & $(-F)_a$ & $-(F_a + \iota(F[a]))$ \\
$0_a = 0$ & $(F + G)_a$ & $(F_a + G_a) + \iota(F[a] \land G[a])$ \\
$1_a = 0$ & $(F \times G)_a$ & $(F_a \times G(a:s)) + \iota(F[a]) \times G_a)$ \\
$X_a = 1$ & $(1/(1 + (X \times F)))_a = -(F(a:s))/(1 + (X \times F(a:s)))$ & \\
\hline
\end{tabular}
\end{center}
We refer to $F[a]$ and $F_a$ as the *syntactic initial output*, respectively the *syntactic stream function derivative*, of $F$ on input $a$.

We now show that $\xi$ indeed ensures that the algebraic semantics coincides with the behavioural semantics of function expressions.

**Proposition 4.5** The map $[\cdot ] : \mathbb{FExpr} \rightarrow \Gamma$ is a homomorphism of Mealy machines from $\langle \mathbb{FExpr} , \xi \rangle$ to $\langle \Gamma , \gamma \rangle$.

**Proof.** We must show that for all $F \in \mathbb{FExpr}$ and all $a \in 2$:

$$[F][a] = F[a] \text{ and } [F_a] = [F]_a.$$  

The proof is by induction on the structure of $F$. We only show the case for $+$ and product; the others can be shown along the same lines (the full proof details are found in the Appendix). In the identities below, $\text{IH}$ refers to the induction hypothesis. Note also that for any $b \in 2$ and $\sigma \in 2^\omega$:

$$[[t(b)](\sigma) = [b].$$  

Let $a \in 2$ and $\sigma \in 2^\omega$:

$$[\mathbb{F} \times \mathbb{G}][a] = ([\mathbb{F} \times \mathbb{G}](a : \sigma))(0) = ([\mathbb{F}](a : \sigma) \times [\mathbb{G}](a : \sigma))(0) = [\mathbb{F}][a] \land [\mathbb{G}][a]$$

$$\text{IH} \iff [\mathbb{F} \times \mathbb{G}][a] = (F \times G)[a].$$

$$[\mathbb{F} \times \mathbb{G}][a][\sigma] = ([\mathbb{F} \times \mathbb{G}](a : \sigma))'(0) = ([\mathbb{F}](a : \sigma) \times [\mathbb{G}](a : \sigma))'(0) = ([\mathbb{F}][a] \times [\mathbb{G}][a])'(0)$$

$$\text{IH} \iff ([\mathbb{F}][a] \times [\mathbb{G}][a])'(0) = (F \times G_a)[\sigma].$$

By Lem. 4.3

$$\text{QED}$$

Since $\langle \Gamma , \gamma \rangle$ is a final Mealy machine, the map $[\cdot ]$ coincides with the unique homomorphism $\text{beh}: \langle \mathbb{FExpr} , \xi \rangle \rightarrow \langle \Gamma , \gamma \rangle$. In other words, we have shown that for all function expressions $F$, $[F] = \text{beh}(F)$.

### 5 Synthesis

A consequence of Proposition 4.5 is that the generated submachine $\langle \langle F \rangle \rangle$ is a realisation of $[F]$. Conceptually, we can construct $\langle \langle F \rangle \rangle$ by computing the transition closure of $\{F\}$ in $\langle \mathbb{FExpr} , \xi \rangle$. However, in general, $\langle \langle F \rangle \rangle$ is neither finite nor minimal. In order to obtain a minimal realisation of $[F]$ we compute $\langle \langle F \rangle \rangle$ modulo equivalence. In practice, this is achieved by reducing function expressions to normal form. We briefly describe these normal forms.
5.1 Normal forms

We call a function expression $F$ integral if it does not contain the inverse operation, and $F$ is closed if it does not contain $s$. The polynomial normal form $\text{pnf}(F)$ of an integral expression $F$ is an analogue of the distributed normal form of polynomials (in the variable $s$). It can be computed in the expected manner by applying identities of commutative rings: (i) distribute $\times$ over $+$, (ii) reduce using identities for $0$ and $1$, (iii) collect terms on powers of $s$, and finally (iv) reduce sums of closed expressions using the identity $X^n + X^m = X^{n+m}$, for all $n \geq 0$. This last identity holds since for all $\alpha \in 2^\omega$, $\alpha + \alpha = X \times \alpha$, cf. equation (3). For example, $\text{pnf}((1 + X) \times (1 + s) + 1) = X^2 + (1 + X) \times s$, and this polynomial normal form is “computed” in the following series of identities:

$$(\begin{array}{l}
((1 + X) \times (1 + s)) + 1 \\
\equiv ((1 + X) \times 1) + ((1 + X) \times s) + 1 \\
\equiv ((1 \times 1) + (X \times 1)) + ((1 \times s) + (X \times s)) + 1 \\
\equiv (1 + X) + (s + (X \times s)) + 1 \\
\equiv (1 + 1 + X) + (1 + X) \times s \\
\equiv X^2 + (1 + X) \times s.
\end{array})$$

Note that in the last step we used that,

$$1 + 1 + X \equiv X^0 + X^0 + X^1 \equiv X^1 + X^1 \equiv X^2.$$ 

Given arbitrary function expressions $F$ and $G$, we can decide whether $F \equiv G$ by first rewriting (using the identities of integral domains) $F$ and $G$ into fractions $P/Q$ and $R/S$, respectively, where $P,Q,R,S$ are integral, and then checking whether $\text{pnf}(P \times S) = \text{pnf}(R \times Q)$. These normal forms are treated in detail in [6].

**Example 5.1** We illustrate by computing (a representation of) $\llbracket [F] \rrbracket$ for the function expression $F = (1 + X) \times s$. For the transition on input $0$ we find that:

$$((1 + X) \times s)[1] = \begin{array}{l}
(0)(1[1] \times (1 \times 0)) \land (1 \times 0) \land 1 = 1. \\
(1 + X) \times s[1] = \begin{array}{l}
(0 + 1) + (1 \times (1 \times s)) + (0 + 1) + (1 \times s) \\
(0 + 1) \times (1 + (X \times s)) + (1 \times s) \\
1 + ((1 + X) \times s) = 1 + F
\end{array}
\end{array}$$

Computing further derivatives and initial output, we find the following minimal realisation of $\llbracket F \rrbracket$:
where \( f = [F] \), \( f_1 = [1 + F] \) and \( f_{11} = [X + F] \).

The normal forms essentially allow us to compute submachines in the final Mealy machine. Still, for arbitrary \( F \in \mathbf{FExpr} \), the least fixed point construction of \( \langle \langle [F] \rangle \rangle \) is not guaranteed to terminate as it is easy to specify functions that have no finite realisation. For example, if we take \( F = s \times s \) and we compute the derivatives \( [F]_0, [F]_{00}, [F]_{000}, \ldots \) we get the sequence \([X \times F], [X^2 \times F], [X^3 \times F], \ldots \) which are all distinct. A similar argument shows that if \( F = 1/(1 + (X \times s)) \), then \([F]\) has infinitely many distinct stream function derivatives.

### 5.2 Rational functions

We now define a class of expressions that specify functions with finite realisations. A **rational function expression** is a function expression of the form

\[
F = \frac{D + (C \times s)}{1 + (X \times E)}
\]

where \( D, C, E \in \mathbf{FExpr} \) are closed, integral function expressions. In other words, \( D, C \) and \( E \) specify constant bitstream functions whose value is of the form \( \text{Bin}(x) \) for some integer \( x \in \mathbb{Z} \). An example of a rational function expression is

\[
F = \frac{(-X) + ((1 + X) \times s)}{1 + (X \times (X + X))}
\]

which specifies the bitstream function

\[
f(\sigma) = \frac{\text{Bin}(-2) + (\text{Bin}(1 + \times) \times \sigma)}{\text{Bin}(1 + 2 \times (2 + 2))} = \frac{\text{Bin}(-2) + (\text{Bin}(3) \times \sigma))}{\text{Bin}(9)}
\]

A function \( f : 2^\omega \to 2^\omega \) is called **rational** if there is a rational function expression \( F \) such that \([F] = f\). Hence the function \( f(\sigma) = \text{Bin}(3) \times \sigma \) specified in Example 5.1 is also rational by taking \( D = E = 0 \) and \( C = 1 + X \). The numeric interpretation of closed, integral expressions will be convenient below.

**Lemma 5.2** A function \( f : 2^\omega \to 2^\omega \) is rational iff there are \( d, m, n \in \mathbb{Z} \) such that \( n \) is odd, and for all \( \sigma \in 2^\omega \)

\[
f(\sigma) = \frac{\text{Bin}(d) + (\text{Bin}(m) \times \sigma)}{\text{Bin}(n)}
\]

**Proof.** This follows essentially from the fact that \( \text{Bin} : \mathbb{Q}_{\text{odd}} \to \mathbf{A}_{2\text{adic}} \) is a homomorphism of integral domains. \( \square \)

To simplify notation, we will leave out the Bin-part, and just write \( f(\sigma) = (d + (m \times \sigma))/n \) whenever \( f(\sigma) = (\text{Bin}(d) + (\text{Bin}(m) \times \sigma))/\text{Bin}(n) \).
Similarly, for \( x \in \mathbb{Z} \), we write \( x(0) \) and \( x' \) instead of \( \text{Bin}(x)(0) \) and \( \text{Bin}(x)' \), respectively. The following technical lemmas will be used to prove that rational functions have finite realisations. Their proofs can be found in the Appendix. The first of these lemmas use the numeric interpretation of rational functions to characterise the immediate derivatives.

**Lemma 5.3** Let \( f \) be a rational bitstream function of the form:

\[
f(\sigma) = \frac{d + (m \times \sigma)}{n}
\]

for integers \( d, m \) and \( n \) with \( n \) odd. For \( a \in \mathbb{Z} \), the stream function derivative \( f_a \) is given by:

\[
(f_a)(\sigma) = \frac{\delta(a) + (m \times \sigma)}{n}
\]

where (in the numeric interpretation)

\[
\delta(0) = \begin{cases} 
\frac{1}{2} d & \text{if } d \text{ even} \\
\frac{1}{2} (d - n) & \text{if } d \text{ odd}
\end{cases}
\]

\[
\delta(1) = \begin{cases} 
\frac{1}{2} (d + m) & \text{if } d(0) = m(0) \\
\frac{1}{2} (d + m - n) & \text{if } d(0) \neq m(0)
\end{cases}
\]

Hence Lemma 5.3 already tells us that the derivatives of a rational function are again rational. The next lemma uses the numeric interpretation to give a bound on the range of \( \delta \)-values that can occur in the stream function derivatives of a rational function.

**Lemma 5.4** Let \( f(\sigma) = \frac{d + (m \times \sigma)}{n} \) be a rational function with \( n > 0 \) odd. For all \( w \in 2^* \), the stream function derivative \( f_w \) is of the form

\[
(f_w)(\sigma) = \frac{\delta(w) + (m \times \sigma)}{n}
\]

where \( \delta(w) \) is an integer such that

\[
\min\{d, -n + 1, -n + m + 1\} \leq \delta(w) \leq \max\{d, m - 1, 0\}.
\]

The crucial properties that make it possible to perform synthesis from rational function specifications are stated in the following proposition.

**Proposition 5.5** For all rational bitstream functions \( f : 2^\omega \rightarrow 2^\omega \),

1. all stream function derivatives of \( f \) are rational,
2. \( \langle\langle f \rangle\rangle \) is finite.

**Proof.** Let \( f(\sigma) = \frac{d + (m \times \sigma)}{n} \) be a rational function. Item 1 of the proposition follows from Lemmas 5.2 and 5.3. To see that item 2 holds, first note that we can always assume that \( n > 0 \) since \( f \) is equal to the function \( g(\sigma) = \frac{-d + (-m \times \sigma)}{n} \). The number of states in \( \langle\langle f \rangle\rangle \) equals the number of distinct \( \delta(w) \)-values in the derivatives of \( f \). By Lemma 5.4 this number is finite.

QED
We can now finally state our synthesis result for rational function specifications.

**Theorem 5.6** For any rational function expression $F$, the Mealy machine $\langle \langle \langle F \rangle \rangle \rangle$ is a finite, minimal realisation of $\langle \langle F \rangle \rangle$, and we can effectively construct a representation of $\langle \langle F \rangle \rangle$ by computing syntactic stream function derivatives and initial output and working modulo equivalence.

In fact, Lemma 5.4 can be used to show that the number of derivatives of a function $f(\sigma) = \frac{d + m \times \sigma}{n}$ is at most $|d| + |m| + |n|$, and in many cases an even tighter upper bound can be given. We refer the interested reader to [6, Ch.3] for more details on this result.

**Example 5.7** We illustrate our synthesis algorithm with the construction of a minimal realisation of the function $f$ specified by $F = X^3 \times s$, i.e., in numeric notation, $f(\sigma) = 8 \times \sigma$ for all $\sigma \in 2^\omega$. For the sake of readability, we will write derivative expressions in their numeric interpretation. For example, the derivative $(X^2 + (X^3 \times s))$ will be denoted $4 + 8\sigma$. The diagram in Figure 2 shows the Mealy machine obtained from $F$ using our algorithm.

![Figure 2: Mealy machine constructed from $F = X^3 \times s$.](image)

At the beginning of the computation, the only state is $8\sigma$. In the first iteration, the immediate derivatives of $8\sigma$ are computed. These are $8\sigma$ and $4 + 8\sigma$, so $4 + 8\sigma$ is a new state. In the second iteration, we compute the immediate derivatives of $4 + 8\sigma$ and find $2 + 8\sigma$ and $6 + 8\sigma$, both of which are new. In the third iteration, we find the new states $1 + 8\sigma$, $5 + 8\sigma$, $3 + 8\sigma$ and $7 + 8\sigma$. In the fourth iteration, we find that all derivatives of the states...
$1 + 8\sigma$, $5 + 8\sigma$, $3 + 8\sigma$ and $7 + 8\sigma$ have already been visited, hence there are no new states after this round, and the algorithm terminates.

**Example 5.8** As yet another example, in Figure 3 we give a minimal realisation of the rational function from equation (4), i.e., $f(\sigma) = ((-2) + (3 \times \sigma))/9$. For a compact presentation, the states are labelled only by the $\delta$-value. For example, the state which realises the function $(1 + (3 \times \sigma))/9$ is labelled just with 1.

![Figure 3: Mealy machine realising $f(\sigma) = ((-2) + (3 \times \sigma))/9$.](image)

Knowing that rational functions have finite realisations, it is natural to ask whether the converse holds, that is, whether all causal bitstream functions that are realised by a finite Mealy machine can be specified by a rational function expression. This question is answered in the negative by the following example.

**Example 5.9** Consider the Mealy machine depicted in the following diagram:

![Diagram](image)

We will show that there is no rational function expression $F$ such that $[F] = beh(q)$. To this end, we first observe that the behaviour of the state $s$ is simply the identity function on bitstreams, hence $beh(s) = [s]$. Suppose, for the sake of arriving at a contradiction, that $F$ is a function expression such that $[F] = beh(q)$, and $F$ is of the form $F = (B + (C \times s))/(1 + (X \times E))$ where $B, C, E \in \text{FExpr}$ are closed, integral function expressions. By Proposition 4.5, $[F]_0 = [F] = beh(q)_0 = beh(s) = [s]$, hence $F_0 \equiv s$. On the other hand, Lemma 5.3 tells us that $F_0 \equiv (D + (C \times s))/(1 + (X \times E))$ for some closed, integral function expression $D$, and hence $(D + (C \times s))/(1 + (X \times E)) \equiv s$. 

17
Consequently, $D \equiv 0$, $C \equiv 1 + (X \times E)$, which implies that $C[0] = C[1] = 1$. From Definition 4.4 of the Mealy machine of expressions it follows that for all $a \in 2$:

\[
F[a] = (B + (C \times s))[a] = B[a] \oplus (C[a] \land s[a]) = B[a] \oplus (1 \land a)
\]

and hence,

\[
F[0] = B[0] \quad \text{and} \quad F[1] = 1 - B[1]
\]

But since $B$ is a closed function expression, $B[0] = B[1]$, and hence by the above $F[0] \neq F[1]$. But $beh(q)[0] = beh(q)[1] = 1$ which contradicts the assumption that $[F] = beh(q)$, and we conclude that no such $F$ exists.

Given the numeric nature of rational function expressions and their high level of abstraction, we do not find it surprising that they cannot specify all finite state Mealy behaviours.

6 Discussion and Related Work

Brzozowski [3] showed how to construct a deterministic finite automaton for a rational expression by computing its finitely many derivatives, herewith lifting the well-known fact that rational languages have a finite number of (left) quotients, to the symbolic level of expressions. Since then, various applications and generalisations have been studied. In [1], Antimirov introduced the notion of partial derivative and used it to construct non-deterministic finite automata. In [13, 15], we reformulated Brzozowski’s original approach in coalgebraic terms and generalised it to formal power series over arbitrary semirings, providing at the same time a generalisation of Antimirov’s results. A similar generalisation to formal power series and rational expressions with multiplicities was found, independently, by Lombardy and Sakarovitch [11].

We have shown how to construct a finite Mealy machine realisation of rational 2-adic functions by a symbolic computation of derivatives. The same principles can be used to perform Mealy synthesis of functions specified in mod-2 arithmetic (cf. [6, Ch. 3]). We expect that the method can also be extended to include bitstream functions specified in the Boolean bitstream algebra, respectively Kleene bitstream algebra, described in [16] alongside the 2-adic and mod-2 bitstream algebras. It would be interesting to combine the operators of these bitstream algebras into “mixed specifications”. Although a Mealy machine of “mixed expressions” can be defined (using the stream differential equations), and various “mixed identities” are proved in [16], it is not clear whether there exists an equivalence of mixed expressions with finite index, which is effectively decidable. Such an equivalence is necessary to generalise symbolic synthesis to mixed specifications.
Closely related to the work presented here is the work in [18] where coalgebras are synthesised from a kind of generalised recursive process specifications. The method is similar to ours in the sense that it relies on a symbolic computation of generated subcoalgebras. This construction is parametric in the functor $T$ which defines the coalgebra type as well as the syntax of the specifications, and so covers many different automaton-like system types (including Mealy machines) in a uniform framework. Instantiating the results of [18] to Mealy machines, we point out the following differences with our work. The syntax of the specification language in [18] is in close correspondence with the semantic structure and specifying rational 2-adic functions would be inconvenient to say the least. On the other hand, the close connection between syntax and semantics ensures that any behaviour of a finite Mealy machine can be specified in their language and vice versa, all specifications have finite realisations. As we have seen in Example 5.9, we do not have such a match between rational function expressions and finite Mealy machines.

The idea of generating behaviour from syntax is possible at a very general level. Such interplay between algebra (syntax) and coalgebra (behaviour) can often be captured by so-called bialgebras for a distributive law (cf. [19, 2]). For example, the stream differential equations for the 2-adic operators define a distributive law of the 2-adic signature over stream behaviour. Other examples of distributive laws are rules in structural operational semantics (cf. [2]), and also regular expressions and deterministic automata form an example of this much more abstract setup (cf. [10]). Such a bialgebraic picture also exists for function expressions and Mealy machines, although in a slightly less direct way than the abovementioned examples. A paper reporting on this result is currently under preparation.

Appendix

Proof of Proposition 4.5. Let $a \in 2$ and $\sigma \in 2^\omega$.

\[
\begin{align*}
[0][a] &= [0](a: \sigma)(0) = 0(0) = 0 = 0[a] \\
[0]_a(\sigma) &= [0](a: \sigma)' = [0]' = [0] = [0_a](\sigma) \\
[1][a] &= [1](a: \sigma)(0) = 1(0) = 1 = 1[a] \\
[1]_a(\sigma) &= [1](a: \sigma)' = [1]' = [0] = [1_a](\sigma) \\
[X][a] &= [X](a: \sigma)(0) = X(0) = 0 = X[a] \\
[X]_a(\sigma) &= [X](a: \sigma)' = X' = [1] = [X_a](\sigma) \\
[s][a] &= ([s](a: \sigma))(0) = (a:\sigma)(0) = a = s[a] \\
[s]_a(\sigma) &= ([s](a: \sigma))' = (a:\sigma)' = \sigma = [s_a](\sigma)
\end{align*}
\]

Note that for any $b \in 2$ and $\sigma \in 2^\omega$: $\llbracket \nu(b) \rrbracket = [b]$.

Minus:

\[
\begin{align*}
[-F][a] &= ([-F](a: \sigma))(0) = (-[F](a: \sigma))(0) = ([F](a: \sigma))(0) = [F][a]. \\
&\text{IH} \\
&\equiv F[a] = -F[a] \\
[-F]_a(\sigma) &= ([-F](a: \sigma))' = (-[F](a: \sigma))' \\
&\equiv -(([F](a: \sigma)' + ([F](a: \sigma))(0))) = -([F]_a + [F][a])(\sigma) \\
&\text{IH} \\
&\equiv [-F]_a(\sigma) = ([F][a] + \iota(F[a]))(\sigma) = \llbracket (-F)_a(\sigma) \rrbracket.
\end{align*}
\]

Sum:

\[
\begin{align*}
[F + G][a] &= ([F + G](a: \sigma))(0) = ([F](a: \sigma) + [G](a: \sigma))(0) \\
&\equiv [F](a: \sigma)(0) + [G](a: \sigma)(0) = [F][a] + [G][a] \\
&\text{IH} \\
&\equiv F[a] + G[a] = (F + G)[a]. \\
[F + G]_a(\sigma) &= ([F + G](a: \sigma))' = ([F](a: \sigma) + [G](a: \sigma))' \\
&\equiv ([F]_a(\sigma) + [G]_a(\sigma)) + ([F][a] \land [G][a]) \\
&\text{IH} \\
&\equiv ([F_a]_a(\sigma) + [G_a](\sigma))(\sigma) + [F][a] \land [G][a] \\
&\equiv ([F_a]_a(\sigma) + \iota(F[a] \land G[a]))(\sigma) \\
&\equiv ([F + G]_a)(\sigma).
\end{align*}
\]
Proof of Lemma 5.3. Let $f(a) = \frac{d + m \times a}{n}$ for integers $d, m$ and $n$ with $n$ odd, and let $a \in 2$. First, using the stream differential equations of Definition 3.1 and the identities of commutative rings, we find by a straightforward calculation that the initial value and stream derivative of a bitstream quotient $\sigma/\tau$ (with $\tau(0) = 1$) are given by:

$$ (\sigma/\tau)(0) = \sigma(0) \quad \text{and} \quad (\sigma/\tau)' = (\sigma' - [\sigma(0)] \times \tau')/\tau \quad (7) $$

We now use (7) to compute $f_\sigma(a)$ for $a \in 2$. The steps marked with (†) use commutativity of $\times$ and $+$.

$$ f_\sigma(a) = \left( \frac{d + m \times (a:\sigma)}{n} \right)' \overset{\dagger}{=} \left( \frac{d + (a:\sigma) \times m}{n} \right)' $$

$$ = \frac{(d + ((a:\sigma) \times m)') - ([d(0) \oplus (a \land m(0))] \times n')}{n} $$

QED
\[
\begin{align*}
&= \frac{d' + \left( (\sigma \times m) + ([a] \times m') + [d(0) \land (a \land m(0))] - ([d(0) \lor (a \land m(0))] \times n') \right)}{n} \\
&\begin{cases}
(\sigma \times m) + ([a] \times m') \\
\frac{(d' + [d(0) \land m(0)]) - ([d(0) \lor m(0)] \times n')}{n}
\end{cases}
\end{align*}
\]

The initial values are computed in a similar manner. Hence we obtain the following equations for the \( \delta(a) \)-value in (5):

\[
\begin{align*}
\delta(0) &= d' - [d(0)] \times n' \\
\delta(1) &= d' + m' + [d(0) \land m(0)] - [d(0) \lor m(0)] \times n'.
\end{align*}
\]

The rest of the proof is now straightforward using (2) (p. 7). If \( d \) is even then \( \delta(0) = d' = \frac{1}{2}d \), and if \( d \) is odd, we get:

\[
\delta(0) = d' - n' = \frac{1}{2}(d - 1) - \frac{1}{2}(n - 1) = \frac{1}{2}(d - n).
\]

When \( d \) and \( m \) are both odd, i.e. \( d(0) = m(0) = 1 \), we have

\[
\delta(1) = d' + m' + 1 = \frac{1}{2}(d - 1) + \frac{1}{2}(m - 1) + 1 = \frac{1}{2}(d + m).
\]

If \( d \) is odd, and \( m \) is even, then

\[
\delta(1) = d' + m' - n' = \frac{1}{2}(d - 1) + \frac{1}{2}m - \frac{1}{2}(n - 1) = \frac{1}{2}(d + m - n).
\]

The remaining cases are proved similarly, details are left to the reader. \( \text{QED} \)

**Proof of Lemma 5.4.** It is a consequence of Lemma 5.3 that the derivatives of \( f \) have the given format (6), since \( f \) is itself of the form required in Lemma 5.3, and hence so are all derivatives of \( f \). We prove by induction on the length of \( w \in 2^* \) that the numeric value \( \delta(w) \) is in the given range. The base case \( (w = \varepsilon) \) is clear. To prove the inductive step, we use the numeric interpretation of derivatives of rational 2-adic functions given in Lemma 5.3. To ease notation, let \( l = \min\{d, -n + 1, -n + m + 1\} \) and \( u = \max\{d, m - 1, 0\} \). Note that \( l \leq 0 \leq u \). Assume as induction hypothesis (IH) that \( l \leq \delta(w) \leq u \). Inequalities obtained from the induction hypothesis will be denoted by \( \leq_{IH} \).

**Induction step for \( \delta(w0) \):** We first consider the case where \( \delta(w) \) is even, and thus \( \delta(w0) = \frac{1}{2}\delta(w) \). We have the following cases:

- if \( \delta(w) \geq 0 \): \( l \leq 0 \leq \frac{1}{2}\delta(w) \leq \delta(w) \leq_{IH} u \).
- if \( \delta(w) < 0 \): \( l \leq_{IH} \delta(w) < \frac{1}{2}\delta(w) < 0 \leq u \).
Now if $\delta(w)$ is odd, then $\delta(w) = \frac{1}{2}(\delta(w) - n)$. To prove the lower bound, we have

$$l \leq -n + 1 \Rightarrow 2l \leq l - n + 1 \leq_{IH} \delta(w) - n + 1,$$

and since $\delta(w) - n + 1$ is odd, it follows that $2l \leq \delta(w) - n$ and hence $l \leq \frac{1}{2}(\delta(w) - n)$. The upper bound follows easily from $\delta(w) - n < \delta(w) \leq_{IH} u$ which implies $\frac{1}{2}(\delta(w) - n) \leq u$, since $u \geq 0$.

Induction step for $\delta(w1)$: If $\delta(w)(0) = m(0)$, then $\delta(w1) = \frac{1}{2}(\delta(w) + m)$. We first prove the lower bound. We have (since $n > 0$),

$$l \leq -n + m + 1 \leq m \quad \text{and} \quad l \leq_{IH} \delta(w)$$

whence $2l \leq \delta(w) + m$, and $l \leq \frac{1}{2}(\delta(w) + m)$. For the upper bound, we have

$$m - 1 \leq u \quad \text{and} \quad \delta(w) \leq_{IH} u$$

whence $\delta(w) + m - 1 \leq 2u$, and $\delta(w) + m - 1$ must be odd, since $\delta(w)(0) = m(0)$. It follows that $\delta(w) + m \leq 2u$, which in turn implies $\frac{1}{2}(\delta(w) + m) \leq u$.

If $\delta(w)(0) \neq m(0)$, then $\delta(w1) = \delta(w) + m - n$. We know that $l \leq -n + m + 1$ and hence $2l \leq l - n + m + 1 \leq_{IH} \delta(w) + m - n + 1$. Since $\delta(w) + m - n + 1$ is odd, it follows that $2l \leq \delta(w) + m - n$, and hence $l \leq \frac{1}{2}(\delta(w) + m - n)$. The upper bound is proven in a similar fashion. We have $m - 1 \leq u$ which implies $\delta(w) + m - n \leq_{IH} u + m - n \leq u + m - 1 \leq 2u$, and it follows that $\frac{1}{2}(\delta(w) + m - n) \leq u$. QED
Centrum Wiskunde & Informatica (CWI) is the national research institute for mathematics and computer science in the Netherlands. The institute's strategy is to concentrate research on four broad, societally relevant themes: earth and life sciences, the data explosion, societal logistics and software as service.

Centrum Wiskunde & Informatica (CWI) is het nationale onderzoeksinstituut op het gebied van wiskunde en informatica. De strategie van het instituut concentreert zich op vier maatschappelijk relevante onderzoeksthema’s: aard- en levenswetenschappen, de data-explosie, maatschappelijke logistiek en software als service.
